This ſeems to argue, that the body did not properly conſiſt of ſuch elements, or that they were not originally contained in it, but were rather produced by the fire.

REDIPATAM, in *Geography*, a town of Hindooſtan, in Marawar; 18 miles N. of Ramadnaporum.

REDIRE *ad Pacem*, in *Law*, is applied to a perſon, whoſe outlawry is reverſed, and who is reſtored to the king's peace.

REDISSEISIN, a diſſeiſin made by him who once before was found and adjudged to have diſſeiſed the ſame man of his lands or tenements; for which there lies a ſpecial writ, called a *writ of rediſſeiſin*. See ASSISE *of Novel Diſſeiſin*, DISSEISIN, and POST-*Diſſeiſin*.

REDMANS, or RADMANS, in Doomſday and other ancient books, are probably the ſame with rod, or rad-knights; *viz.* men who, by the tenure or cuſtom of their lands, were to ride with, or for, the lord of the manor, about his buſineſs.

REDNITZ, in *Geography*, a river of Germany, formed by the union of the Upper and Unter Reſtat, about 5 miles S. of Roth, in Franconia. After receiving in its courſe ſeveral ſtreams, it diſcharges itſelf into the Maine, a little below Bamberg.

REDOLESCO, a town of Italy, in the department of the Mincio; 14 miles W.S.W. of Mantua.

REDON, a town of France, and principal place of a diſtrict, in the department of the Ille and Vilaine; 32 miles S.S.W. of Rennes. The place contains 3783, and the canton 11,620 inhabitants, on a territory of 187½ kiliometres, in 5 communes. N. lat. 47° 39′. W. long. 2°.

REDONDA, an iſland in the Weſt Indies, about 10 miles in circumference, without ports, rivers, or towns. N. lat. 16° 55′. W. long. 62° 20′.

REDONDELA, or Redondillo, a town of Spain, in the province of Galicia, near the weſt coaſt, defended by a ſtrong caſtle; 32 miles W.S.W. of Orenſa.

REDONDO, a rock, about three miles in circumference, between the iſlands of Montſerrat and Nevis, in the Weſt Indies. N. lat. 17° 6′. W. long 61° 35′.

Redondo *Novo*, a town of Benguela. S. lat. 11° 22′. E. long. 13° 45′.

Redondo, *O*, a town of Portugal, in Alentejo; 14 miles E.N.E. of Evora. N. lat. 38° 33′. W. long. 7° 22′.

REDONDOS, a town of Portugal, in the province of Beira; 17 miles S. of Coimbra.

REDOUBLE′, Fr., in *Muſic*, a doubled interval in the octave above a ſingle interval. The octave of the octave, with us, is called the 15th. See Interval.

REDOUBT, or Redoute, *Reductus*, in *Fortification*, a ſmall ſquare fort, without any defence but in front, uſed in trenches, lines of circumvallation, contravallation, and approach; as alſo for the lodging of corps de garde, and to defend paſſages. See Fort.

They are uſually figures of three, four, five, or ſix ſides, encompaſſed with a ditch, and a bank of earth, which conſiſts of two parts, called rampart and parapet.

In marſhy grounds, redoubts are often made of ſtone-work, for the ſecurity of the neighbourhood; their face conſiſts of from ten to fifteen fathoms; the ditch round them from eight to nine feet broad and deep; and their parapets, which are cut into embraſures and merlons, have the ſame thickneſs. See Reduct.

The inner ſides of ſquare redoubts are uſually between the limits of twelve and thirty-two yards; and when they are to be defended by muſketry, the number of men neceſſary to the defence may be thus determined: half the ſide ſquared gives the number of troops; and twice the ſquare root of a given number of men, ſhews the length in yards of the ſide of a ſquare redoubt proper to contain them.

To conſtruct a ſquare redoubt. — Mark out a ſquare, whoſe ſide is adapted to the number of troops allotted for the defence, as A B (*Plate* VII. *Fortification*, *fig.* 5.) for the inſide of the rampart. About this ſquare, at the diſtance of ten or twelve feet, deſcribe another ſquare, whoſe ſide, C D, is the inner boundary of the parapet; make a parapet of about nine or ten feet thick, whoſe outline is the line E F; leave a berm about three or four feet broad, whoſe ſide is G H; and dig a ditch about ſixteen feet wide, and about ſix or ſeven feet deep, which ſhould be rounded before the angles of the redoubt. Make the rampart from four feet to nine or ten feet high; let the parapet be ſix or ſeven feet higher, and let the foot-bank be four feet and a half lower than the crown of the parapet. On that ſide moſt ſecure from the enemy, make a bridge acroſs the ditch, and a paſſage through the rampart, about four or five feet broad when the defence is muſketry, about nine or ten feet broad when cannon are to be uſed; and ſhut up the paſſage by a ſtrong gate. If the redoubt is to be defended by cannon, both the rampart and parapet ſhould be at leaſt five or ſix feet thicker. In order to make the fire pretty nearly equal on all ſides, and ſufficient for defending the angles of the work, M. Clairac has contrived to cut the inſide of the parapet into notches, whoſe two ſides, of a yard each, are at right angles to one another, and make half-right angles with the ſides of the work; the manner of which, and its defence, are plainly ſhewn in the figure, where the lines with dots at the ends repreſent the fire three different ways from the ſame ſide.

For the method of conſtructing flanked redoubts, ſee Fort.

A *detached* redoubt is a kind of work reſembling a ravelin, with flanks, placed beyond the glacis; ſuch as B (*Plate* V. *Fortification*, *fig.* 6.) They are made in order to occupy ſome ſpot of ground which might be advantageous to the beſiegers; and likewiſe to oblige the enemy to open their trenches farther off than they would otherwiſe do. Their diſtance from the covert-way ought not to exceed a hundred and twenty toiſes, that they may be defended by muſket-ſhot from thence. The gorge, *a b*, is forty toiſes; the flanks, *a c*, *b f*, which are perpendicular to the gorge, ten; and the faces, *e d*, *f d*, thirty: the ditch before it is ſix toiſes, ending in ſlopes at both ends; the covert-way, four; the branches of the covert-way about forty-two toiſes long; the faces of the places of arms, *y*, *y*, which are perpendicular to the branches, ten; and the other, which is parallel to them, fourteen. The communication from the covert-way to the redoubt is five or ſix toiſes wide; and there is a traverſe made juſt at the entrance, and another in the middle when it is pretty long. The parapets of this communication terminate in a ſlope or glacis. Robertſon's Marine Fortif. p. 20, &c. Muller's Fort. p. 43, &c. See Arrow.

Redoubts are alſo ſmall works of the ſame form made in a ravelin.

Redoubt, *Caſtle* or *Donjon*. See Reduct.

Redoubts *en Cremaillere*, differ from other redoubts by having the inſide line of the parapet broken, ſo as to reſemble a pot-hook, or the teeth of a ſaw; by which a greater fire can be brought to bear upon the defile than if only a ſimple face was oppoſed to it, and conſequently the paſſage is rendered more difficult.

Redoutes *de Terre*, Fr. redoubts that are haſtily thrown up, and made with earth, for the purpoſe of ſecuring entrenchments, circumvallations, paſſages of rivers, &c.

Redoutes *de Maconnerie*, Fr. redoubts made of maſonwork; generally conſtructed in places where an enemy might derive advantage from eſtabliſhing himſelf; they are likewiſe built upon the ſaliant angles of the glacis.

Redoutes *Caſematées*, Fr. caſemated redoubts, or ſuch as are arched over and made bomb-proof. Thoſe conſtructed for the defence of Gibraltar, and for the ſecurity of Dover caſtle, are of this deſcription.

Redoutes *à Machicoulis*, Fr. are thoſe which are made of brick or ſtone-work ſeveral ſtories high. The higheſt ſtory juts out about one foot beyond the wall that ſurrounds or fronts the redoubt.

REDRESSING, the rectifying or ſetting any thing ſtraight again.

Trees and other plants have a natural faculty of redreſſing themſelves, when, by any external cauſe, they are forced out of the perpendicular.

In the moral ſenſe, to redreſs grievances, is to reform or remove them. The redreſs of injuries is the object with a view to which courts of juſtice are inſtituted in every civilized ſociety; in order to protect the weak from the inſults of the ſtronger, by expounding and enforcing thoſe laws, which define rights and prohibit wrongs. This remedy is, therefore.

therefore, to be fought for by application to thefe courts; that is, by civil fuit or action.

To redrefs a ftag, among hunters, is to put him off his changes.

REDRILL, *To*, in *Military Language*, is to put a foldier through the firft elements of military training. Every foldier, after his return from long abfence, muft be redrilled before he is permitted to act in the ranks of a company.

REDRUTH, in *Geography*, a confiderable market-town in the eaft divifion of the hundred of Penwith, and county of Cornwall, England, is fituated on the road from Launcefton to the Land's-End, at the diftance of 262 miles S.W. from London. It occupies the declivity of an eminence in the very centre of the mining diftrict, and derives its fupport entirely from the mines. Dr. Pryce fuppofes it to have been a town in Saxon times; but if fo, the records of its hiftory during that period have been entirely loft. It is firft mentioned in the year 1332, when William Baffet, the then proprietor of the manor, obtained for the inhabitants the privilege of fairs and markets. In 1502 a fimilar grant was made in favour of John Baffet, efq.; and in Oliver Cromwell's time, Mr. Buller of Morrall procured a charter for a market on Fridays, which was confirmed by king Charles II. At prefent there are two weekly markets, held on Wednefday and Friday; and three annual fairs, chiefly for cattle and ozier manufactures. The tolls of two of thefe fairs and the markets belong to the Buller family; and the other fair to lord de Dunftanville, the defcendant of the Baffets. The increafe of this town, fince the commencement of the copper mines in the laft century, has been as fix to one, as appears by the average of baptifms. According to the population return of 1801, it contained 664 houfes, and 4924 inhabitants; but in 1811 the houfes were returned as amounting to 879, and the inhabitants to 5903 in number.

Redruth confifts chiefly of one long ftreet. The church, the living of which is a rectory, was built, in 1770, by lord de Dunftanville, in the ftead of a more ancient one. This building is fituated about half a mile from the town. Here are the remains of a chapel of eafe, dedicated to St. Rumon, which has been unroofed for many years. In Redruth are meeting-houfes for Quakers and Anabaptifts, befides two for Methodifts in the town, and a third in the north part of the parifh. In 1803, a large fchool-houfe was built here by fubfcription, and a mafter placed in it by the fame means; but the fubfcription having been difcontinued, the fchool is now kept open by the mafter on his own account.

Among the numerous mines in Redruth and the contiguous parifhes of Gwennap, Kenwyn, and St. Agnes, thofe denominated the *Gwennap mines* are confidered to be the principal. Thefe lie to the fouth-eaft of Redruth, in a part of the county where the tin and copper lodes are peculiarly rich, and in fome places interfect each other. The country of the united mines Huel-Virgin, Poldice, and Huel-Unity, is fchiftus; that of Huel-Jewell, Huel-Gorland, and Trefavan, is granite; and it has been remarked, that the metallic veins moftly obey the courfe of the granite mountains, and run very nearly parallel with them. The united mines employ about 600 men, of whom 400 work under ground. The water is drawn off by four immenfe fteam-engines, one of the cylinders of which is nearly feven feet in diameter. The Huel-Virgin mine is 160 fathoms deep, and is extremely productive; but the Huel-Unity and Poldice mines are ftill more rich, and are wrought to fuch advantage, that the proprietors ufually fhare from 16,000*l.* to 20,000*l.* *per annum*. The depth of the Poldice mine is 170 fathoms; but at prefent it is not worked at a lower depth than 140. This is one of the oldeft mines in the county, and yields a yellowifh copper ore, a rofin tin, and a few ftones of galena. The Huel-Gorland mine is 120 fathoms below the furface, and is wrought at the expence of about 1000*l.* a month. The North Down mines, nine in number, occupy an extent of two miles in length, and one in breadth, and have their furplus water carried away by the fame long adit which runs through the Gwennap mines to the Carnon-Stream works.

Befides the mines, there are feveral other objects in the vicinity of Redruth not undeferving of notice. Portreath, about four miles to the north, is a fmall fea-port for the importation of coals and lime, and the exportation of copper ore to the works in Wales. It is defended by a fort, mounting four guns, and was erected by lord de Dunftanville in the year 1782, and is maintained at his expence. Tehidy park, the ancient feat of the Dunftanville family, adjoins Portreath on the fouth-weft. This manor is firft mentioned as being in their poffeffion as early as the year 1100, about thirty years before the marriage of Cecilia de Dunftanville with William Baffet, who carried the Dunftanville eftates to the Baffets. The prefent manor-houfe is of modern erection, confifting of a centre, and four detached pavilions at the angles, the whole conftructed chiefly of Cornifh free-ftone. The principal rooms are decorated with fome good portraits by Vandyke, Kneller, and fir Jofhua Reynolds; and alfo with a few pieces by Rubens, Carlo Dolci, Bononi de Ferrari, Rembrandt, Borgognone, and others of lefs note. The park and pleafure grounds attached to this manfion are very extenfive; containing about feven hundred acres, finely varied by wood and lawn, and appearing like a well-cultivated garden in the midft of a defert.

Weftward from Redruth, about a mile and a half, is Carn-breh hill, which Dr. Borlafe and others contend ought to be regarded as the grand centre of Druidical worfhip in this county, almoft every kind of monument commonly attributed to the Druids being found, as they allege, upon that eminence. How far this opinion is correct, we fhall not pretend to decide; but we may obferve, that feveral late writers maintain, that a part of the fuppofed monuments of religion, *viz.* the caves, are in fact the refult of natural convulfion. No doubt, however, fome of them are artificial, and probably belonged to the Druids; and what feems to corroborate this idea is, the circumftance of Redruth being a corruption for Dre-Druith, which fignifies the Druids' town. On the fummit of this hill is a circular fortification, called the Old Caftle, which appears to have been formerly furrounded by a ftrong wall; and about 300 yards to the eaftward, on a ledge of fuccumbent rocks, ftands Carn-breh caftle, part of which lays claim to a very high antiquity; but the remainder is of comparatively modern date. The rocks upon which this ftructure is erected not lying at all contiguous to each other, are connected by maffive circular arches thrown over the cavities.

On the fouth-weft fide of Carn-breh hill is Pendarves, the feat of John Stackhoufe, efq. It is a large handfome building, fituated on an eminence commanding extenfive views over the weftern parts of the county. In a field contiguous is a large cromlech, compofed of three upright ftones, and an impoft. Clowance, fituated about three miles further to the fouth-weft, has been for feveral centuries a feat of the family of St. Aubin. The houfe is deeply embofomed in wood; and contains, befides feveral pictures of curiofity and value, a large collection of rare and choice prints, accumulated in the portfolios of its prefent poffeffor. Lyfons's Magna Britannia, vol. iii. London, 1814, 4to.

Beauties

Bauties of England and Wales, vol. ii. by John Britton and E. W. Brayley.

REDSEAR. See Iron.

REDSTONE, in *Geography*, a town of Pennfylvania, on the Monongahela; 55 miles N.W. of Pittfburg.

REDUBBORS, thofe who buy ftolen clothes, &c. and, to the end they may not be known, turn them into fome other fafhion, &c. See Frippery, and Regrator.

REDUCE, in *Chemiftry*. See Reduct.

To Reduce *a Place*, in *Military Language*, is to oblige the governor to furrender it to the befiegers by capitulation.

To Reduce *the Circle*, is to reftore or bring back a battalion or company which has been formed in circle to its original pofition in line.

To Reduce *the Square*, is to reftore a battalion or battalions which have been formed in a hollow or oblong fquare to their natural fituation in line or column.

REDUCED Chart. See Chart.

To be Reduced, in *Military Language*, is to be taken off the eftablifhment, or ceafe to receive pay as foldiers. When a regiment is reduced, the officers are generally fent upon half pay. Sometimes, as at the clofe of a war, the corps are reduced, and the officers remain upon full pay. Hence are derived the expreffions *in* and *out* of the break. *In the break* denotes the liability of being reduced: *out of the break* fignifies the certainty of being kept upon the eftablifhment.

To be Reduced *to the Ranks*, is to be taken from a fuperior appointment in a regiment, and to be ordered to the duty of a common foldier. This fometimes happens by way of punifhment, when a ferjeant or corporal mifbehaves. A ferjeant, however, cannot, at prefent, be reduced, except by fentence of a regimental court-martial.

REDUCING Scale, is a thin broad piece of box, with feveral lines and fcales of equal parts upon it; for turning chains and links into acres and rods, by infpection.

It is ufed by furveyors to reduce maps and draughts from one dimenfion to another; it is fometimes alfo called a *furveying fcale*.

REDUCT, Reduit, or *Redoubt*, a military term, fignifying an advantageous piece of ground, intrenched and feparated from the reft of the place, camp, &c. for an army, garrifon, &c. to retire to, in cafe of a furprife. Reduits have been fometimes made for the purpofe of fecuring different pofts in a town independent of its citadel. They were propofed by the celebrated Vauban. See Donjon.

Reduct, in *Building*, a kind of recefs, or little place, taken out of a larger, to make it more uniform and regular; or for fome other convenience, as for a little cabinet afide of a chimney, for alcoves, &c.

Reduct, or *Redux*, among *Chemifts*, is a powder by which calcined metals and minerals are reduced again to their regulus, or pure fubftance.

REDUCTION, Reductio, in the *Schools*, a manner of bringing a term or propofition, which before was oppofite to fome other, to be equivalent to it.

Reduction is effected by the addition or retrenchment of a negative particle. Thus, to reduce this propofition, *no man is an animal*, to be equivalent to its oppofite, *every man is an animal*, I drop the negative, and fay, *man is an animal*. After the like manner might the term *every man* be reduced, by adding the negative and faying, *there is no man*.

Reduction *of Propofitions* is ufed in a more general fenfe, for any expreffion of one propofition, by another propofition equivalent to it.

To a reduction, therefore, there are two propofitions required, the *reduced*, and the *reducing*; which are confidered as the extremes of it, and to be connected in the reduction by means of the particle *that is*; which here has the effect of a copula.

As here, *only animals think; that is, animals think, and nothing befides animals thinks*. Where the propofition preceding the particle is reduced, and the fubject of the reduction; that following the particle reduces, and has the effect of the predicate of the reduction, and the particle *that is* acts as a copula, importing, not barely that the propofition is expreffed by another, but by another equivalent one, or, as it were, the fame.

Reduction *of Syllogifms*, is a regular changing or tranfforming of an imperfect fyllogifm into a perfect one. Or, it is a change of a fyllogifm in refpect of form, by which the neceffity of the illation, or inference, is made more evident.

Reduction obtains in fyllogifms of the fecond and third figure; as alfo in the indirect modes of the firft. By it thefe are all brought to the firft.

There are two kinds of this reduction; the one *direct*, or *oftenfive*, performed merely by a converfion of one or both the premifes, or by a tranfpofition of them; as when *cameftres* is reduced to *celarent*: the other *indirect*, called *per impoffibile*, or *ad abfurdum*; by which the perfon who denies the goodnefs and legitimacy of an imperfect fyllogifm, is reduced to affert or grant fomething abfurd and impoffible, or contradictory to fome other thing maintained by him.

Suppofe, *e. gr.* a perfon granting the premifes of the following fyllogifm, denies the conclufion: *All fraud is prohibited; but fome trading is not prohibited; therefore fome trading is not fraud.* We thus proceed againft him if the fyllogifm be not good, the antecedent is juft, but the confequent falfe; and, therefore, the contrary of the conclufion muft be true: now I take the contrary of the conclufion, which you thus give, *viz. all trading is fraud;* and of that, with the other premife of the former fyllogifm, *viz.* the major, which you likewife grant, make a new fyllogifm; thus, *All fraud is prohibited; all trading is fraud: therefore all trading is prohibited.* But this propofition, *all trading is prohibited*, and the other, *fome trading is prohibited*, which you granted me in the firft fyllogifm, are contradictories.

Reduction, in *Arithmetic*, is the converting of monies, weights, or meafures, into the fame value in other denominations; *e. gr.* pounds into fhillings and pence; or fhillings and pence into pounds.

The reductions of the principal monies, coins, weights, and meafures, ancient and modern, foreign and domeftic, are found under Coin, Weight, Measure, Pound, Foot, &c.

Reduction is of two kinds: 1. *Defcending*, when a quantity is to be brought from a higher denomination to a lower.

This is done by confidering how many of the next lefs denomination are contained in the next greater before, and by that number multiplying the greater.

Thus pounds are reduced into fhillings, by multiplying by 20; fhillings into pence, by multiplying by 12; and pence into farthings, by multiplying by 4.

Troy pounds are reduced into grains, by multiplying by 12, 20, and 24: and avoirdupois hundreds into ounces, by 4, 28, and 16.

2. *Afcending*, when a lower denomination is to be reduced to a higher.

In order to this, the bufinefs is to divide the leaft by fo many of its denomination as are contained in the next greater: thus, 24,720 pence, divided by 12, and the quotient by 20, gives 103 pounds.

If there remain any thing in each divifion, it is refpectively

ively either odd pence, or ſhillings: thus, 6713 pence reduced, give 27*l.* 19*s.* 5*d.* cut off the laſt, the reſt are the pounds required.

To expedite the practice, ſeveral compendious ways of reduction have been invented. See PRACTICE.

Thus, yards are turned into ells by ſubtracting a fifth; and into ells Flemiſh by adding a fifth. Ells Flemiſh are reduced into yards by ſubtracting a quarter. Ells Flemiſh reduced to ells Engliſh by multiplying by 6, and cutting off the right-hand figure.

Great pounds of ſilk of twenty-four ounces are reduced to pounds of fixteen ounces by adding one-half; and pounds of fixteen ounces into pounds of twenty-four by ſubtracting one-third.

REDUCTION *of Decimals.* See DECIMALS.

REDUCTION *of Fractions.* See FRACTIONS.

REDUCTION *of Ratios.* See RATIOS, *Reduction of.*

REDUCTION *of Surds.* See SURDS.

REDUCTION *of Equations.* Various algebraical operations are claſſed under this head by different authors; ſome conſidering it to be the ſame as is otherwiſe, and more properly, called the *ſolution* of equations, or the finding of their roots: ſome define it to be the taking away or exterminating all the unknown quantities except one, otherwiſe called *elimination:* others again, under this head, treat of what is more uſually termed the *transformation* of equations; and others again apply it to the depreſſing of an equation, or the reduction of it to another of lower dimenſions, which latter ſeems to us the only operation that can properly be treated of under the above deſignation. See RESOLUTION, and TRANSFORMATION.

There are but few caſes in which the reduction of an equation can be effected, *viz.* only when a known relation has place amongſt any of its roots, in which caſe the equation will admit of being reduced as many degrees lower, as there are independent conditions known to have place. So that if the relation be only between two roots, which is one condition, the equation may be reduced two degrees; if the relation extend to three roots, it may be reduced three degrees; and ſo on.

The conditions or relations more commonly conſidered, are thoſe in which the roots of an equation form an arithmetical or geometrical progreſſion, and when an equation has any number of equal roots. The two former relations ſeem rather objects of curioſity than utility, as it is not probable that an equation ſhould have ſuch relations obtain between its roots; but with regard to equal roots they may frequently ariſe in the ſolution of various problems. When any geometrical or phyſical problem is propoſed, the number of its poſſible ſolutions is generally limited, and therefore the ultimate reſult ariſing out of ſuch inveſtigation ought to be an equation, the number of whoſe roots agree with the limited number of ſolutions. But it may happen that the analyſt, by not purſuing the beſt mode of operation, is led to an equation of higher dimenſions than is requiſite, in which caſes, upon inveſtigation, it will always be found that his reſulting equation has ſome number of equal roots, which being taken away, will reduce the equation to one of lower dimenſions, which gives the proper number of ſolutions to the original problem. As to the caſes in which the roots of an equation form a geometrical progreſſion, they occur almoſt excluſively in the ſolution of binomial equations, having prime indices, a property which M. Gauſs has turned to a good account in the ſolution of theſe equations. See POLYGON, and RECIPROCAL *Equations.*

Nearly all other relations between the roots of equations are feigned for the purpoſes of framing queſtions, and exercising the ingenuity of authors and their ſtudents.

1. To aſcertain whether a propoſed equation has any equal roots.

Let $x^m + \alpha x^{m-1} + \beta x^{m-2} + \gamma x^{m-3} + \&c. = 0$, be any equation whoſe roots are a, b, c, d, &c. then from the known theory of equations we have

$$x^m + \alpha x^{m-1} + \beta x^{m-2} + \gamma x^{m-3} + \&c. =$$
$$(x-a)\ (x-b)\ (x-c)\ (x-d),\ \&c.$$

And it may be ſhewn alſo, that the equation $m x^{m-1} + (m-1)\alpha x^{m-2} + (m-2)\beta x^{m-3} + \&c. =$

$$\begin{aligned}&(x-a)\ (x-b)\ (x-c)\ \&c. +\\&(x-a)\ (x-b)\ (x-d)\ \&c. +\\&(x-a)\ (x-c)\ (x-d)\ \&c. +\\&(x-b)\ (x-c)\ (x-d)\ \&c.;\end{aligned}$$

that is, it is equal to the ſum of all the m equations that can be formed by the different combinations of the m firſt roots, taking $m-1$ at a time. (See Waring's Meditationes Algebraicæ, cap. 3.) Now if we ſuppoſe the firſt equation to have two equal roots, as, for example, $a = b$, the above products will become

$$x^m + \alpha x^{m-1} + \beta x^{m-2} + \gamma x^{m-3} + \&c. =$$
$$(x-a)\ (x-a)\ (x-c)\ (x-d)\ \&c. \text{ and}$$
$$m x^{m-1} + (m-1)\alpha x^{m-2} + (m-2)\beta x^{m-3} + \&c. =$$
$$\begin{aligned}&(x-a)\ (x-a)\ (x-c)\ \&c. +\\&(x-a)\ (x-a)\ (x-d)\ \&c. +\\&(x-a)\ (x-c)\ (x-d)\ \&c. +\\&(x-a)\ (x-c)\ (x-d)\ \&c.;\end{aligned}$$

where it is obvious that both the one and the other of theſe equations have the ſame factor, *viz.* $(x-a)$.

If the equation had three equal roots, it is equally obvious that both equations would have the common factor $(x-a)^2$; and generally, if the equation had p equal roots, they would both have the common factor $(x-a)^{p-1}$.

Therefore, when it is propoſed to find whether a given equation have equal roots, we muſt from the propoſed equation draw the *derived* equation as above, (which, it will be obſerved, is the ſame as would ariſe from taking the fluxion of the firſt, leaving out of courſe the $\dot{x}$'s,) and find by the uſual methods, whether theſe two functions have any common meaſure; which, if they have, will furniſh us with the equal root ſought; and conſequently the original equation may then be reduced by diviſion to another of two degrees lower dimenſion for two equal roots; of three degrees lower for three, and ſo on.

Exam. 1.—It is required to find the equal roots of the equation $x^3 - 48x - 128 = 0$.

Here the derived equation is $3x^2 - 48 = 0$, and the common meaſure of theſe two functions is $x + 4$; whence -4 and -4 are the equal roots; the third root being $+8$.

Exam. 2.—It is required to aſcertain whether the equation

$$x^4 + 3x^3 - 14x^2 - 12x + 40 = 0$$

have equal roots, and what they are.

Here the derived equation is

$$4x^3 + 9x^2 - 28x - 12 = 0;$$

and the common diviſor of the two is $x - 2$; whence $x = 2, 2$, which are two of the equal roots. Divide now the original equation by $x^2 - 4x + 4$, and we have

$$x^2 + 7x + 10 = 0,$$

whoſe

whoſe roots are -2, and -5; therefore, the four roots of the propoſed equation are $2, 2, -2, -5$.

If the roots of an equation be equal, but with contrary ſigns, the operation is more ſimple. For, in this caſe, we have only to change the ſigns of the roots in the propoſed equation, by changing the alternate ſigns of its co-efficient; and we ſhall thus have two equations, having neceſſarily a common quadratic factor of the form $x^2 - a^2$, which may be found, and the equation depreſſed as before.

Exam. 3.—Required the roots of the equation $x^4 + 3x^3 - 7x^2 - 27x - 18 = 0$, two of which are equal, but with contrary ſigns.

By changing the ſigns of the alternate terms, we have $x^4 - 3x^3 - 7x^2 + 27x - 18 = 0$, the common quadratic diviſor of which is $x^2 - 9 = 0$; whence the equal roots with contrary ſigns are $+3$, and -3. Now dividing the propoſed equation by $x^2 - 9$, we have $x^2 + 3x + 2 = 0$; whence $x = \frac{-3}{2} \pm \sqrt{\frac{1}{4}} = -2$, and -1, which are the other two roots.

On this ſubject the reader ſhould conſult Waring's Meditationes Algebraicæ, cap. 3. See alſo Bonnycaſtle's Algebra, vols. i. and ii.

REDUCTION *of Intereſt of the public Debt.* See FUND.

REDUCTION *of Curves.* See CURVE.

REDUCTION *of a Figure, Deſign,* or *Draught,* is the making a copy of it, either larger or ſmaller than the original, ſtill preſerving the form and proportion.

The great uſe of the proportional compaſſes is in the reduction of figures, &c. whence they are alſo called *compaſſes of reduction.*

There are various methods of reducing figures, &c.; the moſt eaſy is by means of the *pentagraph* (which ſee), or parallelogram: but this has its defects. The beſt and moſt uſual methods of reduction are as follow:

To reduce a figure, as A B C D E (*Plate* XII. *Geometry, fig.* 5.) *into a leſs compaſs.*—About the middle of the figure, as *z*, pitch on a point; and from this point draw lines to its ſeveral angles, A, B, C, &c. then drawing the line *a b* parallel to A B, *b c* parallel to B C, &c. you will have the figure *a b c d e* ſimilar to A B C D E.

If the figure *a b c d e* had been required to be enlarged, there needed nothing but to produce the lines from the point beyond the angles, as *z* D, *z* C, &c. and to draw lines, *viz.* D C, C B, &c. parallel to the ſides *d c*, *c b*, &c.

To reduce a figure by the angle of proportion.—Suppoſe the figure A B C D E (*fig.* 6.) required to be diminiſhed in the proportion of the line A B to *a b* (*fig.* 7.): draw the indefinite line G H (*fig.* 8.), and, from G to H, ſet off the line A B; on G deſcribe the arc H I; ſet off the line *a b* as a chord on H I, and draw G I. Then with the angle I G H you have all the meaſures of the figure to be drawn. Thus to lay down the point *c*, take the interval B C, and upon the point G deſcribe the arc K L; alſo on the point G deſcribe M N; and upon *a*, with the diſtance M N, deſcribe an arc cutting the preceding one in *c*, which will determine the ſide *b c*. And after the ſame manner are all the other ſides and angles to be deſcribed. The ſame proceſs will alſo ſerve to enlarge the figure.

To reduce a figure by a ſcale.—Meaſure all the ſides of the figure, *e. gr.* A B C D E, by a ſcale, and lay down the ſame meaſures reſpectively, from a ſmaller ſcale in the proportion required.

To reduce a map, deſign, or figure, by ſquares.—Divide the original into little ſquares, and divide a freſh paper of the dimenſions required, into the ſame number of ſquares; which are to be larger or leſs than the former, as the map is to be enlarged or diminiſhed.

This done, in every ſquare of the ſecond figure, draw what you find in its correſpondent one in the firſt.

REDUCTION *to the Ecliptic,* in *Aſtronomy,* is the difference between the argument of latitude, as N P (*Plate* XIX. *Aſtronomy, fig.* 10.) and an arc of the ecliptic N R, intercepted between the place of a planet and the node N.

To find the reduction.—The angle of inclination P N R, and the argument of latitude N P, being given, find, by the doctrine of ſpherics, the arc N R; ſubtract N R and N P from each other, the remainder is the reduction.

REDUCTION *into firſt Matter,* is a term which alchemiſts formerly uſed, when they found their ſubſtances putrefy, and grow black.

REDUCTION was more particularly uſed for the converſion of a dry matter into a liquid, particularly into water; which by the alchemiſts was held the principle of all things.

The reduction of metals into their firſt matter, or principles, according to theſe philoſophers, can only be effected by mercury; nothing elſe being able to looſen the fixed ſulphur of metallic bodies, which binds them together.

REDUCTION, in *Metallurgy,* is the decompoſition of a metallic oxyd, ſo as to leave the metal in a ſtate of greater or leſs purity, and exhibiting the luſtre which is ſo eminently characteriſtic of metallic bodies.

Reduction is, for the moſt part, effected by charcoal and a high temperature, either with or without the aſſiſtance of fluxes. For the various modes of reduction in actual practice, ſee the articles of the different metals.

REDUCTION, in *Surgery,* denotes an operation by which a diſlocated, luxated, or fractured bone is reſtored to its former place. Reduction, or *repoſition,* is always to be performed before any remedy be applied.

REDUIT, in *Military Affairs.* See REDUCT.

REDUNDANCY, or REDUNDANCE, a fault in diſcourſe, conſiſting in the uſe of a ſuperfluity of words.

Words perfectly ſynonimous are redundant, and ought to be retrenched. Redundancy neceſſarily makes the ſtyle weak and languid. See PLEONASM.

REDUNDANT HYPERBOLA, in *Geometry,* is a curve of the higher kind, thus called, becauſe it exceeds the conic ſection of that name in the number of its hyperbolic legs; being a triple hyperbola, with ſix hyperbolical legs.

REDUNDANT *Interval,* in *Muſic,* is uſed for an interval exceeding the truth by a comma.

Some apply redundant to an interval exceeding a diatonic interval by a ſemitone minor; but this is more uſually called a ſuperfluous interval. See INTERVAL and SECOND.

REDUPLICATION, in *Rhetoric,* a figure by which a verſe begins with the ſame word as the preceding one ends with. See ANADIPLOSIS.

REDUPLICATION, in *Logic,* is a kind of condition expreſſed in a propoſition, indicating or aſſigning the manner in which the predicate is attributed to the ſubject.

The uſual reduplicative words are *quatenus, as, ſo far as, conſidered as, inaſmuch as,* &c. Hence,

REDUPLICATIVE PROPOSITIONS, are ſuch in which the ſubject is repeated, with ſome circumſtances or condition. Thus, *Men, as men, are rational; kings, as kings, are ſubject to none but God.*

REDUTEA, in *Botany,* ſo called by the late M. Ventenat, in honour of his friend M. P. J. Redouté, one of the moſt accurate and intelligent botanical draughtſmen, and perhaps the fineſt botanical painter, ever known. He is the author of a ſplendid coloured work in folio, on the Liliaceous

liaceous tribe, including ſome other beautiful plants allied thereto, which has already extended to the ſeventh volume; and it is to his pencil that the perfection of moſt botanical works that have appeared in France, for near thirty years paſt, particularly the publications of L'Heritier and Ventenat, is owing.—Venten. Jard. de Cels, 11. Poiret in Lamarck Dict. v. 4. 87.—Claſs and order, *Monadelphia Polyandria*. Nat. Ord. *Columniferæ*, Linn. *Malvaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, double, permanent: the outer of many minute leaflets: inner much larger, of one leaf, in five very deep ſegments. *Cor.* Petals five, roundiſh kidney-ſhaped, imbricated obliquely, united at the baſe to each other, and to the column of the ſtamens. *Stam.* Filaments numerous, united below into a conical tube, ſubdivided and branched above; anthers kidney-ſhaped. *Piſt.* Germen ſuperior, ovate, ſimple; ſtyle thread-ſhaped, ſwelling upwards, about as long as the ſtamens; ſtigmas three, obtuſe. *Peric.* Capſule ovate, of three cells and three valves, the partitions from the middle of each valve. *Receptacles* of the ſeeds three, inſerted into the baſe of the capſule, alternate with the valves, and nearly equal to them in length, linear, bearing ſeeds on each edge. *Seeds* ſix or eight in each cell, obovate, minutely ſtalked, inſerted in two rows on the receptacle, each clothed with denſe wool.

Eſſ. Ch. Calyx double; the outer of many minute leaves; inner in five deep ſegments. Stigmas three. Capſule of three cells and three valves. Seeds enveloped in wool. Receptacles three, linear, unconnected with the valves.

Obſ. Ventenat conſiders the three diſtinct receptacles, as affording the moſt eſſential diſtinction, between this and every other malvaceous genus. The woolly ſeeds, moreover, diſtinguiſh it from all except *Goſſypium*, whoſe large three-leaved outer calyx is abundantly different from *Redutea*.

The only known ſpecies is

1. R. *heterophylla*. Various-leaved Redutea. Vent. Jard. de Cels, t. 11.—Diſcovered by Riedlé in the iſland of St. Thomas, and raiſed in M. Cels's garden at Paris. The plant is herbaceous and annual, and M. Ventenat ſeemed to think it might ſerve to decorate our flower-borders, like other annuals of very hot climates, in the open air, being, we preſume, raiſed on a hot-bed in the ſpring. Every part of the herbage is beſprinkled with ſmall, whitiſh, fringed ſcales, readily ſeen with a magnifying glaſs. The *root* is ſpindle-ſhaped, yellowiſh. *Stem* erect, twelve or fifteen inches high, about the ſize of a gooſe-quill, angular, pithy, branched, leafy, dark green, many-flowered. *Leaves* alternate, on longiſh ſtalks, ſpreading widely, ovate, undivided or three-lobed, entire, an inch or inch and half long; paler beneath. *Stipulas* minute, awl-ſhaped, deciduous. *Flowers* large, handſome, ſulphur-coloured, with a dark purple radiating ſpot at the baſe of each petal, ſolitary, erect, on long, ſimple, axillary ſtalks. Segments of the inner *calyx* nearly linear, half as long as the petals. *Style* hairy. *Capſule* the ſize of a filberd. Wool of the *ſeeds* of a dirty grey. —We have not heard of this plant in any Engliſh collection.

REDUVIA, in *Surgery*, a word uſed by ſome for a whitlow, and by others for a painful crack, or other diſorder about the nails, either of the fingers or toes.

REDUX, in *Chemiſtry*. See Reduct.

REDWAETH Bay, or *Traeth Coch*, in *Geography*, a bay on the N. coaſt of the iſland of Angleſey. N. lat. 53° 17'. W. long. 4° 25'.

REDWITZ, a town of Bavaria, in the biſhopric of Bamberg; 4 miles N.N.W. of Kunſtadt.

Redwitz, a town of Germany, in the principality of Culmbach; 4 miles N. of Bayreuth.

REDWOOD River, a river of America, which runs into the Wabaſh, N. lat. 40° 16'. W. long. 87° 5'.

REE, or Re, in *Commerce*. See Rees.

Ree, *Lough*, in *Geography*, an expanſion of the waters of the river Shannon, in Ireland, between the county of Roſcommon and the counties of Longford and Weſtmeath, reaching from Laneſborough nearly to Athlone, with ſeveral iſlands, and in ſome places three miles broad.

REED, in *Botany*. See Arundo.

The root of the *arundo donax* of Dioſcorides, attracts any matter lodged in wounds, if powdered and applied to them with wine; or if it is taken freſh and reduced to powder with an onion, or mixed with honey. (Oribas de Morb. Cur. lib. iii. cap. 32.) It alſo removes pains ariſing from diſlocation of limbs, and carries off pains in the hips. The green leaves cut and applied, are ſaid to cure the eryſipelas. Poor people boil the flowers in water or in beer, which they mix with honey, and drink, after being filtrated, to cure coughs, oppreſſions of the breaſt, and conſumptions. The ancients made flutes and other muſical inſtruments of the reed. James's Med. Dict.

Reed, *Barr*. See Sparganium.

Reed, *Indian flowering*. See Canna.

Reed *Mace*. See Typha.

Reed, in *Agriculture*, the name of an aquatic plant, infeſting boggy lowlands or meadows on the ſides of rivers.

The beſt method of deſtroying reeds, is by draining the land; for if the drains be cut deeper than their roots it will take away their nouriſhment, and, conſequently, deſtroy them. Aſhes, or ſoot, will likewiſe ſometimes kill them; and ſo will ploughing up the land, and laying it in high ridges. They always indicate a deep good moiſt ſoil, as a bad one will not nouriſh or ſupport them. There are many different ſorts of reeds, but thoſe of the more ſtrong and tall kinds are often of much uſe in thatching the different ſorts of farm buildings, where other better kinds of coverings are ſcarce, and theſe abundant. There is alſo a ſort of reed found in Huntingdonſhire, and ſome of the adjoining counties, that is very valuable for the purpoſe of laying plaſter floors with. In other ſituations, reeds of the other kinds may be met with, that may be found uſeful for different purpoſes either of the farmer or in the arts. In ſuch ſituations they may be cultivated with advantage as an article of profit: and it may often be more beneficial than to have them deſtroyed, eſpecially where they are of a valuable nature, and where the land is of too moiſt and boggy a quality to be ever fully reclaimed and brought into either the ſtate of good arable or meadow ground. Slips on the ſides of large rivers or brooks are likewiſe, frequently, the moſt advantageouſly, conveniently, and profitably kept under reed crops, as the overflow of the waters prevent their being uſefully managed in any other manner. There are other ſituations, as thoſe about the borders of large ponds, lakes, and other waters, where they may be preſerved with far greater propriety than having them deſtroyed, provided even that can be accompliſhed without difficulty, as not any thing more valuable can in general be raiſed in ſuch places. They are, however, by no means to be continued wherever any better crop will grow and ſucceed.

Reed is alſo a term applied to ſuch ſtraw of the wheat or rye kinds as has not been bruiſed by threſhing or in any other way.

Reed *Hedge*, in *Gardening*, that ſort of hedge fence which is formed from reeds. They are a ſort of temporary internal fences made with theſe dried materials which may be had cheap, and be expeditiouſly formed into hedges by the aſſiſt-

 ance

ance of poſt and railing, being of great utility for occaſional uſe in gardens, to incloſe particular internal ſpaces of ground, ſo as to afford ſhelter to certain ſeedling plants, both in nurſeries and large kitchen gardens; and in ſome nurſeries, to form places of ſhelter for many ſorts of ſeedling trees and ſhrubs, &c., which being tender whilſt young, require the ſhelter of a fence in winter to break off ſevere or cutting blaſts two or three years, till they gradually gather ſtrength and a greater degree of hardineſs. They are alſo uſeful in training ſeveral ſorts of wall-fruit-trees againſt, to form them for rows, or what are called trained trees; admitting of planting trees againſt each ſide of them, ſix, eight, or ten feet aſunder. See NURSERY.

And in large open kitchen-gardens they are occaſionally made uſe of to incloſe the melonary, or place for raiſing early melons and cucumbers in, and often as croſs internal fences, under which to form warm borders for the purpoſe of raiſing various early crops of eſculents.

The proper ſort of reeds for theſe fences are the dried ſtems of the common marſh reed, which grows in great plenty by river ſides, and in lakes, and marſhy places, furniſhing a crop of ſtems annually fit to cut in autumn, when they ſhould be bound in bundles, and ſtacked up, or houſed, to remain for uſe.

Theſe fences are ſometimes erected in fixed ranges, and ſometimes formed into moveable pannels. In the firſt mode, ſome ſtout poſts ſhould be placed ſix or eight feet aſunder, and five or ſix high, and from poſt to poſt carry two or three ranges of flat thin railing, one range near the bottom, another near the top, and a third in the middle; againſt this railing, the reeds muſt be placed about two inches thick, having other railing fixed directly oppoſite; ſo that the reeds being all along between the double railing, the bottoms reſting either upon a plate of wood, or let into the ground, but the former is preferable; and as ſoon as one pannel is formed, the railing ſhould be nailed as cloſe as poſſible, driving ſome long ſpike-nails through each double railing, or binding them with ſtrong withy bands, or tar rope-yarn, but nailing is the beſt, in order to bring them as cloſe as may be, to ſecure the reeds firmly in the proper poſition; the top ſhould be cut even afterwards.

In the better method, a frame-work of railing ſhould be prepared as above, each pannel ſix or eight feet long, and the reeds fixed therein as before directed; then, where they are intended to be placed, poſts muſt be ranged ſix or eight feet diſtant to ſupport the different pannels. Or ſometimes the pannels may be placed inclining againſt the wall or other fence, in time of ſevere weather, when the borders are narrow. Theſe ſorts of fences are now however in much leſs uſe in gardening than formerly.

REED *Ronds*, in *Rural Economy*, a provincial word, ſignifying plots or beds of reed, or the ſwamps in which they grow.

REED, *Ezekiel's*. See EZEKIEL'S *Reed*.

REED, *Calamus*, likewiſe denotes a Jewiſh meaſure, otherwiſe called canna.

REED, in the *Manufactory of Tapeſtry*. See TAPESTRY.

REED *Sparrow*, in *Ornithology*. See EMBERIZA *Schoeniculus*.

REED *Point*, in *Geography*, a cape on the W. coaſt of the iſland of Antigua. N. lat. 17° 12′. W. long 61° 36′.

REEDHAM. See REEPHAM.

REEDS, in a *Fire-ſhip*, are made up in ſmall bundles of about twelve inches in circumference, cut even at both ends, and tied each with two bands. There are two kinds of them; the long, which are four feet; and the ſhort, which are two feet five inches in length. Some of them are ſingly dipped, *i. e.* at one end, the reſt are dipped at both ends, in a kettle of melted compoſition. After being immerſed about ſeven or eight inches in this preparation, and then drained, they are ſprinkled over with pulverized ſulphur upon a tanned hide. See FIRE-*ſhip*.

REEDSBOROUGH, in *Geography*. See READSBOROUGH.

REEDSTOWN. See STRONG.

REEDY CREEK, a river of New Jerſey, which runs into the Atlantic, N. lat. 39° 55′. W. long. 74° 16′.

REEDY *Iſland*, an iſland of America, in the Delaware river, 50 miles below Philadelphia, and 20 miles from Bombay Hook, about three miles long and not more than one-fourth of a mile wide. This iſland was formerly banked in, but is now under cultivation, and overflowed in high tides. It is the rendezvous of outward-bound ſhips in autumn and ſpring, waiting for a fair wind. Here is a ſecure harbour at Port Penn, where piers have been erected by the ſtate of Pennſylvania. On each ſide of the iſland is a channel; but veſſels, eſpecially of the larger kind, chooſe to keep the eaſtern ſide.

REEDY *River*. See SALUDA.

REEDY *River Shoal*, a poſt-town of America, in Greenfield county, South Carolina.

REEF (*reef*, Dutch), in *Navigation*, denotes a certain portion of a ſail, comprehended between the top or bottom, and a row of eyelet-holes parallel to it. The intention of the reef is to reduce the ſurface of the ſail in proportion to the increaſe of the wind; for which purpoſe there are ſeveral reefs parallel to each other in the ſuperior ſails, by which they may be ſtill farther diminiſhed, in order to correſpond with the ſeveral degrees of the gale. The top-ſails of ſhips are uſually furniſhed with four reefs, parallel to the yard; and there are always three or four reefs parallel to the foot of thoſe main-ſails and fore-ſails which are extended upon booms; a circumſtance common to many of the ſmall veſſels. Falconer.

A *bag-reef* is the fourth, or lower, reef of a top-ſail. A *balance-reef* croſſes boom-main-ſails diagonally, from the nock to the end of the upper reef-band on the after-larch. This is uſed to contract the ſails in a ſtorm.

REEF alſo denotes a chain of rocks, lying near the ſurface of the water.

REEF-*Band*, in *Sea Language*, a piece of canvas, ſewed acroſs the ſail, to ſtrengthen it in the place where the eyelet-holes of the reefs are formed.

REEF-*Hanks*, ſhort pieces of log-line or other ſmall line, faſtened at certain diſtances to form the reefs of boom-ſails.

REEF-*Tackle*, is a rope which paſſes from the deck to a block at the top-maſt head, and thence to another block at the topſail-yard-arm, where it communicates with another rope, called its *pendant*, that runs downwards through a hole in the yard, and is afterwards attached to a cringle, a little below the loweſt reef. It is uſed to pull the ſkirts of the reefs cloſe up to the extremities of the top-ſail yards, in order to lighten the ſail, the weight of which would otherwiſe render it very difficult to perform this operation. Falconer.

REEF *Iſland*, in *Geography*, a ſmall iſland in the Eaſt Indian ſea, about 50 miles from the W. coaſt of Sumatra. S. lat. 4°. E. long. 101° 3′.—Alſo, a ſmall iſland in the Eaſt Indian ſea, near the N. coaſt of the iſland of Celebes. N. lat. 0° 8′. E. long. 122° 48′.

REEFING, in *Sea Language*, the operation of reducing a ſail, by taking in one or more of the reefs, which is performed by lines, points, or knittles. The top-ſails are always

always, and the courfes generally, reefed with points, which are flat braided pieces of cordage, whofe lengths are nearly double the circumference of the yard. Thefe, being inferted in the eyelet-holes, are fixed in the fail by means of two knots in the middle, one of which is before, and the other behind the reef-band. In order to reef the top-fails with greater facility and expedition, they are lowered down, and made to fhiver in the wind, which confiderably relaxes their tenfion. The extremities of the reef are then drawn up to the yard-arms by an affembly of pullies communicating with the deck, termed the *reef-tackle*; and they are fecurely faftened to the yard-arms by fmall cords, called *earings*. The fpace of fail, comprehended in the reef, is then laid fmoothly over the yard, in feveral folds or doubles; and the whole is completed by tying the points above the yard, fo as to bind the reef clofe up to it. The courfes of large fhips are reefed either with points or fmall cords, which are thence called *reef-lines*. In the latter cafe, the line is paffed fpirally through the eyelet-holes of the reef, and over the head of the fail alternately, and afterwards ftrained as tight as poffible. It muft be obferved, however, that the reef-line is fometimes paffed round the yard, and fometimes only round the head of the fail; and each of thefe methods has its advocates. But if it fhould appear effential to prevent the friction by which a fail is galled between the line and the yard, and as the rope-bands are fufficient to fuftain the effort of the fail, it is better to pafs the line only round the fail, provided that the turns are inferted through the roband legs; a circumftance carefully practifed by every fkilful failor. The fame reafon may be alleged in favour of tying the points of the courfes in the fame manner; *i. e.* the after-end of the point fhould be thruft forward between the head of the fail and the yard; and the fore-end of the faid point fhould come aft over the head of the fail and alfo under the yard; and thus croffed over the head of the fail, the point fhould be extended, and the two ends brought over the yard; and tied on the upper fide of it as ftraight as poffible.

When a fail is reefed at the bottom, it is done by knittles, which, being thruft through the eyelet-holes of it, are tied firmly about the fpace of canvas of which the reef is compofed, and knotted on the lower fide of the bolt-rope. Thefe knittles are accordingly removed as foon as the reef is let out. Falconer.

REEK, in *Rural Economy*, a term provincially ufed for ftack. See STACK and RICK.

REEK-*Stavel*, a term applied to a frame of wood placed on ftone, on which the mow or ftack is raifed. It is fometimes written *Reek Staffold*.

REEL, in the *Manufactories*, a machine ferving for the office of reeling.

There are various kinds of reels; fome very fimple, others very complex. Of the former kinds, thofe moft in ufe are,

1. A little reel, held in the hand, confifting of three pieces of wood, the biggeft and longeft whereof (which does not exceed a foot and a half in length, and a quarter of an inch in diameter,) is traverfed by two other pieces difpofed different ways.

2. The common reel, or windlace, which turns upon a pivot, and has four flights, traverfed by long pins, or fticks, on which the fkain to be reeled is put; and which are drawn clofer or opened wider, according to the fkain.

Other reels ufed in particular arts, are explained under their particular articles; as the reel ufed in milling of filk, under the article MILLING; and that in the reeling or winding of filks, under the article of SILK, &c.

REELS, to reel ropes on from a fix-thread ratline to a two-inch rope, have four ribs fixed at each end in a flat circular piece of wood; and round the edges are blades, or handles, to turn them: one of the circular pieces is called the *head*, and is made to flide off for taking the coil away. They turn on an iron fpindle, and are from ten to thirty-fix inches long, and from twelve to eighteen inches diameter. The *Bench-reel* ufed by fail-makers is fimilar to a fpinning-wheel, and is ufed to expedite winding the twine from the fkains to the twine-reel. *Log-reels* have feveral ribs fixed in a circular piece of board at each end, and turn or run upon a fpindle, having a handle at one end. (See LOG.) *Twine-reels*, ufed by fail-makers, are fhort cylindrical pieces of wood, hollowed in the middle to receive the twine, with a hole through the middle for the fpindle. Thofe ufed by rope-makers have four oak bars, about eighteen inches long, framed together at the ends on a wooden fpindle; one of the bars flides, for the conveniency of taking off the twine. The *Yarn-reel* confifts of a circular board faftened horizontally on the middle of a piece of oak four inches fquare, and fixteen long, with a hole through its middle to receive a bolt, on which it turns as its axis, and is ufed to wind fpun-yarn off the coil. The *Hand-reel* is a narrow board, with three or four holes at each end, in which pegs are fixed for reeling marline and other lines.

REELFOOT, in *Geography*, a fmall navigable river of America, in Tenneffee, which difcharges itfelf into the river Miffifippi, about 35 miles S. of the Ohio. It is 30 yards wide feven miles from its mouth. One of its branches rifes on the borders of Kentucky.

REELING, in the *Manufactories*, the winding of thread, filk, cotton, or the like, into a fkain, or upon a bottom, to prevent its entangling.

It is alfo ufed for the charging or difcharging of bobbins, or quills, to ufe them in the manufacture of different ftuffs, as thread, filk, cotton, &c.

Reeling is performed different ways, and by different engines.

REEM, in *Zoology*. See RHINOCEROS *Unicornis*.

REEMING, a term ufed by caulkers for opening the feams of the planks with reeming-irons, that the oakum may be more readily admitted. To make any hole larger is alfo termed reeming.

REEMING-*Irons*, are the largeft irons ufed by caulkers in opening the feams.

REEMSTOWN, or REAMSTOWN, in *Geography*, a fmall poft-town of America, in Lancafter county, Pennfylvania, fituated on a ftream which runs into Calico creek, a water of Coneftoga, which falls into the Sufquehannah; 26 miles N.E. of Lancafter.

REEN, a river of Norway, in the province of Drontheim, which runs into the Glomme; 20 miles N. of Opfal.

REEN *Moffa*, a name ufed by fome for the mountain coralloides, or rein-deer mofs.

REENBERG, THEOCARUS, in *Biography*, a celebrated Danifh poet, was born at Viborg in 1656, where he was educated. In 1680 he fet out on his travels into foreign countries, after having undergone an examination by the theological faculty, and he returned to Denmark in 1682. In 1703 he was appointed fourth judge in Jutland. In 1730 he became counfellor of juftice, and he died in 1742. His poetical works were publifhed at Copenhagen in 1769, by his grandfon Tielmann, with a preface by Kofod Anker, and annotations by Luxdorph. Gen. Biog.

REENSKLOSSER, in *Geography*, a town of Norway; 12 miles N.N.W. of Drontheim.

RE-ENTERING Angle, in *Fortification*. See Angle, and Construction, *according to M. Vauban's first method*.

RE-ENTRY, in *Law*, the refuming or retaking that poffeffion which any one had lately forgone.

As, if I make a leafe of land or tenement, I do thereby forego the poffeffion: and if I condition with the leffee, that for non-payment of rent at the day, it fhall be lawful for me to re-enter; this is as much as if I conditioned to take again the lands, &c. into my own hands, and to recover the poffeffion by my own act, without the affiftance of judge or other procefs. But words in a deed give no re-entry, if a claufe of re-entry be not added. (Wood's Inft. 140.) All perfons who would re-enter on their tenants for non-payment of rent, are to make a demand of the rent; and, to prevent the re-entry, tenants are to tender their rent, &c. (1 Inft. 201.) If there is a leafe for years, rendering rent, with condition, that if the leffee affigns his term, the leffor may re-enter; and the leffee affigneth, and the leffor receiveth the rent of the affignee, not knowing or hearing of the affignment, he may re-enter, notwithftanding the acceptance of the rent. (3 Rep. 65. Cro. Eliz. 553.) See Rent. A feoffment may be made upon condition, that if the feoffor pay to the feoffee, &c. a certain fum of money at a day to come, then the feoffor to re-enter, &c. Litt. § 322. See Entry and Use.

REEPHAM, in *Geography*. See Repham.

REER County. See Rire.

REERSOE, in *Geography*, a fmall ifland of Denmark, in the Great Belt, near the coaft of Zealand. N. lat. 55° 32′. E. long. 11° 7′.

REES, Reis, or *Reas*, in *Commerce*, monies of account in Portugal, 1000 of which make a milreis or milree. In the notation of accounts, the milrees are feparated from the rees by a croffed cypher, called "Cifraon," and the milrees from the millions by a colon; thus Rs . 2 : 700 ⊕ 500, means 2700 mil. and 500 rees. The crufado of exchange, or old crufado, is 400 rees; the new crufado, 480 rees; the teftoon, 100; the vintin or vintem, 20 rees. Thus the milree is $2\frac{1}{2}$ old crufados, $2\frac{1}{12}$ new ditto, 10 teftoons, or 50 vintins. The gold pieces, coined before 1722, are now 20 *per cent.* higher than their original value; fo that the old dobras, coined at 20,000 rees, are worth 24,000; the lifbonnoines or moidores, coined at 4000 rees, are worth 4800; and the halves and quarters in proportion: but few of thefe coins are now in circulation. The gold coins, ftruck fince 1722, are the dobra of 12,800 rees; the meia dobra, Joanefe, or Portugal piece of 6400 rees; the half Joanefe, of 3200; the dezefeis teftoons, of 1600; the quatindo, of 1200; the oito teftoons, of 800; the old crufado, of 400, now very fcarce; and the new crufado, of 480 rees. The filver coins are new crufados, of 480 rees; halves, quarters, and eighths, or pieces of 240, 120, and 60 rees; teftoons of 100, and halves of 50; and vintins of 20 rees. There are alfo copper pieces of 10, 5, 3, and $1\frac{1}{2}$ rees. The pieces coined in Brazil, called patacas, of 600 and 640 rees, are current only in that country, and their intrinfic value is 10 *per cent.* lefs than that of the Portugal coins. There is, befides, a gold milree, ftruck for the Portuguefe poffeffions in Africa, and alfo a filver coin, of the value of 12 macutas, or 600 rees; the macuta being a money of account, worth 50 rees. The Spanifh patacas, or dollar, are reckoned at Lifbon at 830 rees, more or lefs.

Portuguefe gold coins are 22 carats (the mark fine being 24 carats), wrought gold is $20\frac{1}{2}$ carats, and gold duft from $21\frac{3}{4}$ to 22 carats fine. The finenefs of filver is expreffed in dinheiros and grains, the mark fine being 12 dinheiros, and the dinheiro fubdivided into 24 grains. Silver coins are 10 dinheiros 19 grains fine, and wrought filver $10\frac{1}{4}$ fine. The rate of coinage of gold and filver coins is as follows: 8 dobras of 12,800 rees, 16 Joanefes of 6400 rees, 32 half Joanefes of 3200 rees, 64 dezefeis teftoons, 128 oito teftoons, or 256 old crufados, are to weigh a Portuguefe mark of gold, 22 carats fine. Hence (the mark being $3542\frac{2}{5}$ Englifh grains) the dobra contains $442\frac{4}{5}$ grains; the piece of 6400 rees $221\frac{2}{5}$ grains of Englifh ftandard gold, and the other pieces in proportion. Thefe coins, moreover, are not, in general, exactly 22 carats fine; but there is a remedy which amounts from $\frac{1}{32}$ to $\frac{3}{32}$ of a carat; and the new crufados are found to be only $21\frac{27}{32}$ carats fine. The filver coin is 10 din. 19 gr. as above; and the mark is coined into $13\frac{1}{3}$ new crufados; hence the new crufado weighs $345\frac{3}{5}$ Portuguefe grains, or $265\frac{2}{3}$ Englifh grains; halves, quarters, and eighths, in proportion. It, therefore, contains $258\frac{1}{2}$ grains of Englifh ftandard filver. The gold piece of 6400 rees is worth 35*s.* 11*d.* fterling; and the old crufado, 2*s.* 3*d.*; and thus the milree, valued in gold, is worth $67\frac{1}{4}$*d.* fterling. The new filver crufado is worth about 2*s.* 9*d.* fterling; and, therefore, the milree, valued in filver, is worth $68\frac{3}{4}$*d.* fterling. Gold is to filver as 16 to 1.

At Bombay each quarter of a rupee is divided into 100 rees. See Rupee.

Rees, in *Geography*, a town of the duchy of Cleves; 8 miles E. of Cleves. N. lat. 51° 47′. E. long. 6° 20′.

Rees *ul Ain*, or *Refaina*, a town of Afiatic Turkey, in the province of Diarbekir; 80 miles S. of Diarbekir.

REETZ, a town of the New Mark of Brandenburg; 50 miles N.E. of Cuftrin. N. lat. 53° 18′. E. long. 15° 56′.

REEVE, in *Ornithology*, the name of a bird which is the female of the *avis pugnax*; the male of which, from the long feathers round his neck, is called the *ruff*. See Tringa *Pugnax*.

Reeve *of a Church*, is the guardian of it, or the churchwarden.

So *fhire-reef* is the fheriff, or guardian of a county; and *port-reeve*, the warden of a port or haven.

REEVE-LAND. See Reveland.

REEVING, in the *Sea Language*, is the putting a rope through any hole, as the channel of a block, &c. Hence, to pull a rope out of a block, is called *unreeving*.

RE-EXCHANGE, in *Commerce*, a fecond payment of the price of exchange, or rather the price of a new exchange, due upon a bill of exchange that comes to be protefted; and to be refunded the bearer, by the drawer or indorfer. See Exchange.

The occafion of re-exchage is, when the bearer of a bill of exchange, after protefting it, for want either of acceptance, or of payment, borrows money on his own promife, bond, or the like; or draws a bill of exchange in the place where the payment was to be made, on the perfon who furnifhed the firft for which he pays a fecond exchange; which, being added to the firft already paid, the drawer of the firft bill is anfwerable for two exchanges, properly called *exchange* and *re-exchange*.

The bearer of a protefted bill has a right to recover both the one and the other on the drawer. Yet the fimple proteftation which the bearer makes in the act of proteft, that he will take up a like fum at re-exchange, for want of his bill being accepted or paid, is not fufficient to entitle him to demand the reimburfement of his re-exchange, unlefs he make it appear, that he has actually taken up money in the place on which the bill was drawn.

Otherwife the re-exchange will only amount to the reftitution of the firft exchange, with intereft, the expences of protefting, and thofe of the journey, if there have been any.

If a bill of exchange, payable to the bearer or order, come to be protefted, the re-exchange is only due upon the drawer for the place where the remittance was made, not for thofe places where it may have been negociated; at leaft the drawer has a right to be refunded his re-exchange for thofe places by the indorfer.

Indeed, the re-exchange is due from the drawer upon all places where a power of negociation is given by the bill; and upon all others, if the power of negociating be indefinite.

Laftly, the intereft of the re-exchange, of the expences of the proteft, and the journey, are only due from the day of the demand.

It is fuppofed to be the Gibelins driven out of Italy by the faction of the Guelphs, and fheltered at Amfterdam, who firft eftablifhed the cuftom of re-exchange, on pretence of the interefts, damages, and expences they underwent, when the bills given them for the effects they had been obliged to abandon, were not accepted, but came to be protefted.

RE-EXTENT, in *Law*, a fecond extent made upon lands or tenements, on complaint that the former extent was partially made. See EXTENT.

REFAH, in *Geography*, a town of Egypt, on the coaft of the Mediterranean, anciently called "Raphia," (which fee); 18 miles N.E. of El Arifh.

REFECTION, REFECTIO, among *Monks* and *Ecclefiaftics*, a fpare meal or repaft, juft fufficing for the fupport of life.

REFECTION is alfo ufed, in *Ancient Authors*, for a duty or fervice incumbent on any perfon to provide meals for ecclefiaftics, or even for princes.

REFECTORY, or REFECTUARY, *Refectorium*, a fpacious hall in convents, and other communities, where the monks, nuns, &c. take their refections or meals in common.

The refectory of the Benedictines of St. George at Venice, defigned by Palladio, is one of the fineft in the world. Daviler.

REFERENCE, in *Writing, &c.* a mark relative to another fimilar one in the margin, or at the bottom of the page, where fomething, omitted in the text, is added; and which is to be inferted either in reading or copying. A copyift muft be very expert at taking references.

References are alfo ufed in books, where things being but imperfectly handled, the reader is directed to fome other part or place where they are more amply explained.

Dictionaries are full of references, denoted by *fee* or *vide*.

By means of thefe references the dictionary writer fettles a correfpondence between the feveral parts of his work, and may give his dictionary moft of the advantages of a continued treatife.

Indices or tables are only references to the feveral parts of the work where the feveral matters are handled.

REFERENCE, in *Law*, denotes the fending of any matter by the court of chancery to a mafter; and by the courts at law to a prothonotary, or fecondary, to examine and report to the court. (2 Lil. Abr. 432.) If a matter in difference be referred to the fecondary, and one of the parties will not attend at the time appointed, after notice given, to hear the bufinefs referred; the other party may proceed in the reference alone, and get the fecondary to make his report without hearing of the party not attending. (2 Lill. 342.) If a queftion of mere law arifes in the courfe of a caufe in chancery, as whether, by the words of a will, an eftate for life or in tail is created, or whether a future intereft devifed by a teftator fhall operate as a remainder on an executory devife; it is the practice of that court to refer it to the opinion of the judges of the court of king's bench, or common pleas, upon a cafe ftated for that purpofe, in which all the material facts are admitted, and the point of law is fubmitted to their decifion; who thereupon have it folemnly argued by counfel on both fides, and certify their opinion to the chancellor: and on fuch a certificate the decree is ufually founded. It feems that the mafter of the rolls, fitting for the chancellor, may make fuch reference; but not when fitting at the rolls. 2 Bro. C. C. 88.

The court of exchequer is both a court of law and of equity: therefore, if a queftion of mere law arifes in the courfe of the exercife of its equitable jurifdiction, the barons will decide upon it in that fuit, without referring it to another jurifdiction. Bl. Comm. iii.

REFERENDARY, REFERENDARIUS, in *Ancient Cuftoms*, an officer who exhibited the petitions of the people to the king, and acquainted the judges with his commands.

An officer of this kind, Spelman obferves, we had in England, in the time of the Saxons. The like office was afterwards difcharged by others, called mafters of requefts.

REFINING, in *Metallurgy* and *Affaying*. In the former it fignifies the means of obtaining metals from their ores, and from any other impurities, natural or artificial: for which fee the metals under their refpective heads. In the latter it is employed for afcertaining the quantity of the noble metals in the different alloys: for which fee CUPEL; where the methods of refining in the furnace ars fully treated. And for the humid procefs called *parting*, fee GOLD.

It may be proper here to obferve, that although the procefs of parting by nitric acid is ftill practifed, we are inclined to recommend the method propofed by Bergmann, which confifts in diffolving the alloy of gold and filver in nitro-muriatic acid. The filver falls to the bottom in the ftate of muriate of filver, and the gold is precipitated by the green fulphate of iron. The gold, by this means, is obtained perfectly pure, which is feldom the cafe in the procefs of parting. The trouble of tefting to know what filver to add to the alloy, to make the gold equal to one-fourth of the filver, will be faved, and, with heat, the nitro-muriatic acid diffolves the gold quite as foon as the filver is diffolved in the common method. The muriate of filver, which is eafily feparated by wafhing, may be readily reduced by heating it with foda in an iron crucible. The foda combines with the muriatic acid, and is fublimed in white fumes.

REFINING *of Sugar*. This operation is begun by feveral ftrong lixiviums or leys of lime-water and eggs, fhells and all, mixed and beaten together.

The firft refining is performed in the Caribbees, and other places, where the fugar-canes are cultivated; and only ferves to make the brown or coarfe fugars.

When thefe are imported into Europe, the fugar-bakers take them up, and refine them farther, by a fecond operation, or rather a repetition of the firft.

To render the fugar very fine, fit for confections, &c. they give it a third refining; in which they only ufe the whites of eggs and their fhells beaten together, and thrown into the melted fugar; which is called *clarifying the fugar*. See SUGAR.

REFINING *of Salt-petre*. The falt being put into an earthen or iron veffel, as much fpring-water is poured on it as fuffices to diffolve it. The veffel is then put over a gentle fire; and as foon as the water begins to boil, alum powder is thrown into it: the proportion is, one pound of alum to one hundred and twenty-eight pounds of falt-petre; and a little vinegar is added. As it boils, the fcum is to be taken off; and it is to be evaporated till a pellicle appears on it, and then fet to fhoot.

For

For the refining of other matters, as camphor, cinnabar, fulphur, falt, borax, &c. fee CAMPHOR, CINNABAR, SULPHUR, SALT, &c.

REFIRTH VOE, in *Geography*, a bay on the E. coaft of the ifland of Yell. N. lat. 60° 58′. W. long. 1° 25′.

REFITTING, in *Sea Language*, denotes the repairing of any damages which a fhip may have fuftained in her fails and rigging, by battle or tempeftuous weather.

REFLECTED RAY. See RAY.

REFLECTED *Vifion*. See REFLEX and VISION.

REFLECTING, or REFLECTIVE *Dial*, is a fort of dial, which fhews the hour by means of a thin piece of looking-glafs plate, duly placed to caft the fun's rays to the top of a ceiling, on which the hour-lines are drawn.

REFLECTING *Microfcope*. See MICROSCOPE.

REFLECTING *Level*. See LEVEL.

REFLECTING *Telefcope*. See TELESCOPE.

REFLECTION, or REFLEXION, in *Mechanics*, the return, or regreffive motion of a moveable, occafioned by the refiftance of a body, which hindered its purfuing its former direction.

It is controverted whether there be any moment's reft or interval between the incidence and the reflection. For the affirmative ftand the Peripatetics, and all who conceive the reflected motion to be different from the incident one of the fame body. The motion of incidence, according to thefe authors, is wholly loft, and deftroyed, by the refiftance of the obftacle ftruck againft; and the moveable is thus rendered abfolutely quiefcent in the point of contact, till a new motion of reflection is produced in it, from a contrary caufe.

The Cartefians affert the negative; abfolutely denying any reft at all between the incidence and reflection: urging, that if the motion were once deftroyed, though but for a moment, there would be nothing to excite it again; but the body would perfevere in that new ftate, as much as if it had been at reft a thoufand years.

Accordingly Rohault, and others, define reflection to be no other than a change of determination; or a continuation of the former motion in a new direction.

As, fay they, a pendulum, when arrived at its greateft fweep, does not ftop; fo a hard body, by ftriking on another hard one, does not reft, but purfues its motion the contrary way, according to the eftablifhed law of nature; and this from the immediate influence or impulfe of the caufe that firft moved it. But this doctrine is now generally fet afide.

Reflection is conceived, by the lateft and beft authors, as a motion peculiar to elaftic bodies, whereby, after ftriking on others which they cannot remove, they recede, or turn back by their elaftic power.

On this principle, it is afferted, that there may be, and is, a period of reft between the incidence and the reflection; fince the reflected motion is not a continuation of the other, but a new motion, arifing from a new caufe or principle, *viz*. the power of elafticity.

It is one of the great laws of reflection, that the angle a reflected body makes with the plane of a reflecting obftacle, is equal to that in which it ftruck on that obftacle. For the feveral laws of motion obferved in the reflections of bodies, fee PERCUSSION.

REFLECTION *of the rays of light*, in *Optics*, is a motion of the rays, by which, after impinging on the folid parts of bodies, or rather, after a very near approach to them, they recede, or are driven from them.

When rays of light arrive at a furface, which is the boundary of two mediums not homogeneous, they continue their progrefs without deviating from thofe planes in which their former paths lay, and which are perpendicular to the furface of the mediums, but they no longer retain the fame direction, a part of them, and fometimes nearly the whole, being reflected back from the furface, while the remaining part is tranfmitted and refracted, or bent. No inftance occurs of the abrupt change of the denfity of a medium, without a partial reflection of the light paffing either into the denfer, or into the rarer medium; and the more obliquely the light falls on the furface, the greater, in general, is the reflected portion. No body is fo black as to reflect no light at all, and to be perfectly invifible in a ftrong light; although at the furface feparating two very rare bodies, as two kinds of gas, the reflection is too faint to be perceptible; but in this cafe the feparation is feldom perfectly abrupt. The quantity of light reflected, when other circumftances are equal, appears to be always greateft when the difference of the optical or refractive denfity of the two fubftances is the greateft. Thus, the reflection from the common furface of glafs and water is much weaker than from a furface of glafs expofed to the air. Metals, in general, reflect a great proportion of the light falling on them; and even the reflection from the common furface of glafs and mercury appears to be but little weaker than the reflection from the furface of mercury immediately expofed to the air, fo that the optical denfity of the metals muft be exceedingly great. It appears, alfo, that a portion of the light falling on a reflecting furface, is always tranfmitted to a certain depth, notwithftanding the apparent opacity of any large maffes of the fubftance. Thus, if we cover a fmall hole of a window-fhutter with the thinneft leaf-gold, we fhall find that it tranfmits a greenifh light, which muft have paffed the reflecting furface, but which, if the gold had been but one ten-thoufandth of an inch in thicknefs, would have been wholly interrupted, and probably in the fame manner as by paffing through 700 feet of water. See LIGHT and REFRACTION.

The reflection of the rays of light from the furfaces of bodies, is the means by which bodies become vifible.

And the difpofition of bodies to reflect this or that kind of rays moft copioufly, is the caufe of their being of this or that colour.

The reflection of light from the furfaces of mirrors, makes the fubject of *catoptrics;* which fee. See alfo MIRROR.

The reflection of light, fir Ifaac Newton has fhewn, is not effected by the rays ftriking on the very parts of the bodies; but by fome power of the body equally diffufed throughout its whole furface, by which it acts upon the ray, attracting or impelling it without any immediate contact.

This power he fhews to be the fame, by which, in other circumftances, the rays are refracted; and by which they are at firft emitted from the lucid body. See REFRACTION.

The arguments he produces to prove this are as follow: 1. Becaufe the furfaces of polifhed glaffes, which to the eye appear fmooth, are yet, in reality, very rugged and uneven, (polifhing being nothing but the grating, fcratching, and breaking off the coarfer protuberances, by means of fand, glafs, putty, tripoli). If the rays of light, therefore, were reflected by ftriking on the folid parts of the glafs, the reflections would never be fo accurate as we find they are, but the rays would even be as much fcattered by the moft polifhed glafs, as by the rougheft. It remains, therefore, a problem how glafs, polifhed by fretting fubftances, can reflect light fo regularly as it does; which problem is fcarcely otherwife to be folved, than by faying, that the reflection of a ray is effected, not by a fingle point of the reflecting body, but by some power of the whole body, evenly diffused all over its surface, and by which it acts on a ray without immediate contact; for that the parts of bodies do act upon light at a distance, is already shewn under the articles INFLECTION and LIGHT.

2. If the colours, separated by a prism placed at the entrance of a beam of light into a darkened room, be successively cast on a second prism placed at a greater distance from the former, in such manner as that they all fall alike, or with an equal obliquity, upon it; the second prism may be so inclined to the incident rays, that those which are of a blue colour shall be all reflected by it; and yet those of a red colour pretty copiously transmitted. Now, if the reflection were caused by the parts of the air or glass, we would ask, why, at the same obliquity of incidence, the blue should wholly impinge on those parts so as to be all reflected; and yet, the red find pores enough to be, in a great measure, transmitted.

3. Where two glasses touch one another, there is no sensible reflection; and yet we see no reason why the rays should not impinge on the parts of the glass, as much when contiguous to other glass, as when contiguous to air.

4. When the top of a water bubble, by the continual subsiding and exhaling of the water, grows very thin, there is such a little, and almost insensible quantity of light reflected from it, that it appears intensely black; whereas round about that black spot, where the water is thicker, the reflection is so strong, as to make the water seem very white. Nor is it only at the least thickness of thin plates or bubbles, that there is no manifest reflection, but at many other thicknesses, gradually greater and greater. For, in one of our author's observations, the rays of the same colour were, by turns, transmitted at one thickness, and reflected at another thickness, for an intermediate number of successions: and yet, in the superficies of the thinned body, where it is of one thickness, there are as many other parts for rays to impinge on, as where it is of any other thickness.

5. If the red and blue rays, separated by a prism, fall successively on a thin plate of any pellucid matter, whose thickness increases in continual proportion, (such as a plate of air between two glasses, the one plane, and the other a little convex,) the same plate will, in the same part, reflect all the rays of one colour, and transmit all those of the other; but, in different parts, will reflect the rays of one and the same colour at one thickness, and transmit them at another; and thus alternately, and *in infinitum*. Now, it can never be imagined that at one place the rays, which, for instance, exhibit a blue colour, should happen to strike on the solid parts, and those which exhibit a red, to hit on the void parts of the body; and at another place, where the body is either a little thicker, or a little thinner, that, on the contrary, the blue should hit on the pores, and the red upon the solid parts.

6. In the passage of light out of glass into air, there is a reflection as strong as in its passage out of air into glass, or rather a little stronger, and by many degrees stronger than in its passage out of glass into water. Now, it seems improbable, that air should have more reflecting parts than water or glass: but if that should be supposed, yet it will avail nothing; for the reflection is as strong, or stronger, when the air is drawn from the glass by the air-pump, as when it is adjacent to it. If any should here object, on Descartes's hypothesis, that, though the air be drawn away, there is a subtle matter remaining to supply its place, which, being of a denser kind, is better fitted for the reflection of light than any other body; besides that we have elsewhere shewn such subtle matter to be fictitious, and that, supposing its existence, and its reflecting power, no light could ever have been propagated, but must have been all reflected back to the lucid body, immediately after it was first emitted, the following experiment does evidently convict it of falsity.

7. If light, in its passage out of glass into air, strike more obliquely than at an angle of forty or forty-one degrees, it is then wholly reflected: if less obliquely, it is in great measure transmitted. Now, it is not to be imagined, that light at one degree of obliquity should meet with pores enough in the air to transmit the greater part of it, and at another degree should meet with nothing but parts to reflect it wholly; especially considering, that, in its passage out of air into glass, how oblique soever be its incidence, it finds pores enough in the glass to transmit a great part of it. If any suppose, that it is not reflected by the air, but by the utmost superficial parts of the glass, there is still the same difficulty: besides, that such a supposition is unintelligible, and will also appear to be false, by applying water behind some part of the glass, instead of air; for so in a convenient obliquity of the rays, suppose of forty-five or forty-six degrees, at which they are all reflected, where the air is adjacent to the glass, they shall be in great measure transmitted where the water is adjacent to it; which argues, that their reflection or transmission depends on the constitution of the air and water behind the glass, and not on the striking of the rays upon the parts of the glass, the rays not being reflected until they have reached the last part of the surface, and have begun to go out. For if, in going out, they fall upon a surface of oil and water, they proceed, the attraction of the glass being balanced by an equal force the contrary way, and prevented from having its effect by the attraction of the liquor adhering to it: but if the rays, in passing out of this last surface, fall into a vacuum, which has no attraction, or into air, which has but little, not enough to counterbalance the effect of the glass in this case, the attraction of the glass draws them back, and reflects them.

This will appear still more evident by laying two glass prisms, or the object-glasses of two telescopes, the one plane, and the other a little convex, upon each other, so as they may neither touch, nor yet be too far apart; for that light which falls on the hinder surface of the first glass, where the glasses are not above $\frac{1}{1000000}$th part of an inch apart, will be transmitted through the surface, and through the air or vacuum between the glasses, and will pass into the second glass; but if the second glass be taken away, then the light passing out of the second surface of the first glass into the air or vacuum, will not proceed, but will return into the first glass, and be reflected.

Whence it follows, that the rays are drawn back again by some force in the first glass, there being nothing else to occasion their return. And hence too it follows, that the reflection is not effected by means of any subtle matter contiguous to the hinder surface, according to the principles of Descartes; since that matter ought to reflect them when the glasses were nearly contiguous, as well as when the second glass is quite removed.

Lastly, if it be asked, how some of the rays come to be reflected, and others transmitted; and why they are not all alike reflected, supposing the reflection owing to the action of the whole surface? the same great author shews, that there are, both in the rays of light, and in the bodies themselves, certain vibrations (or some such property) impressed on the rays, by the action either of the luminary that emits them, or of the bodies that reflect them; by means of which it happens that those rays, in that part of their vibration

which

which confpires with the motion of the parts of the body, enter the body, are refracted and tranfmitted; but thofe in a contrary part of their vibration are reflected.

Add, that every ray of light, in its paffage through any refracting furface, is put into a certain tranfient conftitution or ftate, which, in the progrefs of the ray, returns at equal intervals, and difpofes the ray, at each return, to be eafily tranfmitted through the next refracting furface; and between each return, to be eafily reflected by it.

Thefe alternate difpofitions, which fir Ifaac Newton calls *fits of eafy reflection*, and of *eafy tranfmiffion*, he accounts for by fuppofing, that they are occafioned by the vibrations of a fubtle fluid, in which the ray paffes, which happening to move fafter than the rays, when a ray is in that part of the vibration which confpires with its motion, it paffes through; but when in the contrary part of the vibration, it is beat back again: whence every ray is fucceffively difpofed to be eafily reflected, or eafily tranfmitted, by every vibration which overtakes it.

He alfo thought that thefe vibrations might be excited by the mutual action and re-action of light, of bodies and of this medium, at the inftant of reflection or refraction; fo that, in fact, he fuppofes two caufes of this difpofition to be reflected or tranfmitted, when rays of light arrive at any new furface. One of them is the regular vibration of the etherial medium, affecting them through the whole of their progrefs from the luminous body; and the other the tremulous motion, or irregular vibration of the fame medium at the furfaces of bodies, occafioned by the action and re-action between light and them: for this laft caufe can hardly be fuppofed to affect the whole etherial medium equally, and produce the regular returns of thefe fits in every ray.

M. Bofcovich fuppofes with Newton, that the fits of reflection or tranfmiffion affect the rays themfelves, in the whole of their paffage from the luminous body, but that they arife from an alteration in their form, by means of the elafticity of their component parts, having been originally driven from the luminous body by a force which acted more ftrongly on the hinder parts than on the reft of the mafs, and thereby put them into a vibratory motion. He alfo fuppofes, that the intervals of the fits of eafy reflection and tranfmiffion may be different in different rays, on the three following accounts. 1. The rays that are differently refrangible have different velocities, at leaft after refraction; fo that, though the fits fhould return at equal intervals, it will affect different rays in different parts of their progrefs. 2. The unequal action between the points that compofe the fame particle of light may make a difference in their ofcillations, at the time of changing their medium. And laftly, rays coming in different inclinations to the new furface, the internal motions of thefe points will be in different directions with refpect to the furface, and confequently the whole mafs of the medium will act upon all the points differently. Bofcov. Theoria, p. 232.

Upon the whole, fays Dr. Prieftley, is it not more probable that the rays of light are tranfmitted from the fun, with an uniform difpofition to be reflected or refracted, according to the circumftances of the bodies on which they impinge; and that the tranfmiffion of fome of the rays under the fame circumftances, apparently, with others that are reflected, is owing to the minute vibrations of the fmall parts of the furfaces of the mediums through which the rays pafs; vibrations that are independent of action and re-action between the bodies and the particles of light at the time of their impinging, though probably excited by the action of preceding rays. As to the tranfmiffion or reflection of certain kinds of light only, producing colours in thin plates, the caufe may be this; *viz.* that every particle of the medium has a great number of equal alternate intervals of attraction and repulfion, relatively to the particles of light; but that thefe intervals are of different magnitudes, according as the particles of light are of different colours. Now if the thicknefs of any tranfparent medium in which the particles of matter are uniformly placed is fuch, that the attracting intervals of the extreme particles, as well as the repelling intervals, coincide with one another, *i. e.* attracting with attracting, and repelling with repelling, in regard to any one kind of rays, *e. g.* the red; by the united force of thefe extremes, (all the intermediate particles of the medium mutually deftroying each other's effects,) thefe rays will be reflected. But where the plate is of an intermediate thicknefs between this and the next thicknefs, where the attracting intervals coincide, attracting with attracting, and repelling with repelling, the attracting intervals will coincide with the repelling ones, and the repelling ones with the attracting ones, and thefe mutually deftroying one another's effects, thefe rays will pafs on freely, and be tranfmitted. But as the intervals of attraction and repulfion are different for differently coloured rays, the thicknefs of the plates at which thefe coincidences will or will not happen, in the differently coloured rays, will be different. So that it appears probable, fays Dr. Prieftley, in conformity to a doctrine firft fuggefted to him by Mr. Michell, that the whole myftery of coloured plates depends upon the attractions and repulfions of the particles of the bodies that compofe them, affecting different rays in a different manner, according to their thicknefs. Hift. &c. of Light and Colours, p. 309, &c. See COLOURS *of thin Laminæ*, &c. and RINGS *of Colours*.

Sir Ifaac Newton concludes his account of the reflection of light with obferving, that if light be reflected not by impinging on the folid parts of bodies, but by fome other principle, it is probable that as many of its rays as impinge on the folid parts of bodies are not reflected, but ftifled and loft in the bodies. Otherwife, he fays, we muft fuppofe two kinds of reflection; for fhould all the rays be reflected which impinge on the internal parts of clear water or cryftal, thofe fubftances would rather have a cloudy colour than a clear tranfparency. To make bodies look black, it is neceffary that many rays be ftopped, retained, and loft in them; and it does not feem probable, that any rays can be ftopped and ftifled in them, which do not impinge on their parts: and hence, he fays, we may underftand, that bodies are much more rare and porous than is commonly believed. However, M. Bouguer difputes the fact of light being ftifled or loft by impinging on the folid parts of bodies. See ABSORBING.

For other facts and obfervations relating to the fubject of this article, fee LIGHT. See alfo RAYS *of Light*, and RAYS *of Heat*.

REFLECTION, in *Catoptrics*, is the return of a ray of light from the polifhed furface of a fpeculum or mirror, as driven thence by fome power refiding in it.

The ray, thus returned, is called a *reflex*, or *reflected ray*, or a *ray of reflection*; and the point of the fpeculum, whence the return commences, is called the *point of reflection*.

Thus the ray A B (*Plate* I. *Optics*, *fig.* 3.) proceeding from the radiant A, and ftriking on the point of the fpeculum B, being returned thence to C, B C reprefents the *reflected ray*, and B the *point of reflection*; in refpect of which A B reprefents the *incident ray*, or *ray of incidence*, and B the *point of incidence*.

Again, a line C G drawn from any point, as C, of the reflected

reflected ray B C, perpendicular to the speculum, is called the *cathetus of reflection*, or *cathetus of the eye*: as a line A F, drawn from the radiant perpendicular to the speculum, is called the *incidence*.

Of the two angles which the reflected ray B C makes with the mirror, the smallest, C B E, is called the *angle of reflection*: as of the two angles the incident ray makes with the speculum, the smallest, A B D, is called the *angle of incidence*.

If the mirror be either concave or convex, the smallest angles the ray makes with the tangent to the point of reflection and incidence, are the angles of reflection and incidence.

The angle C B H, which the reflected ray makes with a perpendicular to the point of reflection, is called the *inclination of the reflected ray*: as the angle A B H is called the *inclination of the incident ray*.

Reflection, *general laws of.*—I. *If a ray of light be reflected from a speculum of any form, the angle of incidence is ever equal to the angle of reflection.* This law obtains in percussions of all kinds of bodies; and consequently must do so in those of light. See *Laws of* Percussion; see also Angle.

It might therefore be here assumed as an axiom: but it is of that importance, and its demonstration so beautiful, that we cannot omit it. Suppose, then, D C (*Plate* XVII. *Optics, fig.* 14.) an incident ray, propagated from the radiant D: here, though the motion of the ray be simple, yet its determination in the line D C, being oblique with respect to the obstacle, is really compounded of two determinations; the one along D E, the other along D G.

The force along D C, therefore, is equal to the two forces along D G and D H. But the obstacle G F only opposes one of the determinations: *viz.* that along D G (for it cannot oppose a determination parallel to itself, as D E): therefore, only the force along D G will be lost by the stroke, that along D H or G C remaining entire. But a body perfectly elastic (such as we suppose the ray of light) will recover by its elasticity the force it lost by the shock.

The ray, therefore, will recover the force D G or C H: thus, retaining both its forces, and both its former determinations H C and C F, after percussion, it will be impelled along C F and C H by the same forces as before along D H and D G. By its compound motion, therefore, it will describe the right line C E, and that in the same time as D C; and H E and D H will be equal, as being described by the same force. Now, the two triangles D C H and C H E are equal, and consequently their similar angles are equal. Since then $HCA = HCF$; D C A, the angle of incidence, is equal to E C F, the angle of reflection. Q. E. D.

This law is confirmed in light by an easy experiment. For a ray of the sun falling on a mirror, in a dark room, through a little hole, you will have the pleasure to see it rebound, so as to make the angle of reflection equal to that of incidence. See Camera *Obscura*.

The same may be shewn various other ways: thus, *e. gr.* placing a semicircle F *i* G, (*Plate* I. *Optics, fig.* 3.) on a mirror D E, its centre on B, and its limb perpendicular to the speculum; and assuming equal arcs, F *a* and G *e*, place an object in A, and the eye in C: then will the object be seen by a ray reflected from the point B. And if B be covered, the object will cease to be seen.

For the conclusions drawn from this general doctrine of reflection, see *the doctrine of* Mirrors, &c.

II. *Each point of a speculum reflects rays falling on it, from each part of an object.* See *the doctrine of* Mirrors, &c.

III. *If the eye* C, *and the radiant point* A, *change places, the point will continue to radiate upon the eye, in the same course or path as before.*

For if the object be removed from A to C, it will still radiate on its former point of reflection, B; but there can be but one right line drawn between the two points G and D; and the rays are right lines. Therefore, that which was before the ray of reflection, will now be the ray of incidence; and since it will be reflected under the same angle as that under which it fell, that which was before the ray of incidence, will now be the ray of reflection. So that the object removed to C, will radiate on the eye placed in A, by the right lines C B and B A. Q. E. D.

Hence, an object is seen by the reflected ray A B, with the eye placed in A, the same as if the eye were in C, and the object in A.

The truth of this theorem is so easily confirmed by experiment, that some, with Euclid, assume it as a principle, and demonstrate the great law of reflection from it. Thus: suppose the angle of incidence a little greater than the angle of reflection, then will the angle A B F be greater than C B E. Wherefore, changing the places of the eye and the object, the angle C B E will become the angle of incidence; and therefore C B E greater than A B F by the supposition. So that the same angle A B F will be both greater and smaller than the other, C B E; which being absurd, A B F cannot be greater than C B E. The same absurdity will follow, if you suppose the angle of incidence less than the angle of reflection. Since then the angle of incidence can neither be greater nor less than that of reflection, it must be equal to it.

IV. *The plane of reflection, that is, the plane in which the incident and reflected rays, and also the angles of incidence and of reflection, are found, is perpendicular to the surface of the speculum; and in spherical specula, it passes through the centre.*

Hence the cathetus, both of incidence and reflection, is in the plane of reflection.

That the *plane of reflection is perpendicular to the speculum*, is assumed by Euclid, Alhazen, and others, as a principle, without any demonstration; as being evident from all observation and experiment.

V. *The image of an object seen in a mirror is in the cathetus of incidence.* This the ancients assumed as a principle; and hence, since the image is certainly in the reflected ray, they inferred, it must appear in the point of concourse of the reflected ray, with the cathetus of incidence; which indeed holds universally in plane and spherical mirrors, and usually also in concave ones, a few cases only excepted, as is shewn by Kepler.

For the particular laws of reflection, arising from the circumstances of the several kinds of specula, or mirrors, plane, concave, convex, &c. see them laid down under the article Mirror.

Reflection, *Caustic by.* See *Caustic* Curve.

Reflection *of Heat.* See Heat, and Rays *of Heat.*

Reflection *of Cold.* See Cold.

Reflection *of Sound.* See Sound.

Reflection *of the Moon*, is a term used by some authors for what we otherwise call her *variation*, being the third inequality in her motion, by which her true place out of the quadratures differs from her place twice equated. See Moon and Variation.

Reflection is also used, in the Copernican system, for the distance of the pole from the horizon of the disc; which

which is the fame thing as the fun's declination in the Ptolemaic fyftem.

Reflection is alfo ufed figuratively for an operation of the mind, by which, turning as it were back upon itfelf, it makes itfelf, and its own operation, its object; and confiders or contemplates the manner, order, and laws, which it obferves in perceiving, reafoning, willing, judging, doubting, believing, &c. and frames itfelf new ideas of the relations difcovered in them.

REFLECTOIRE Curve. See Curve *Reflectoire.*

REFLECTOR *for Light-houfes*, a combination of a number of fquare plane glafs mirrors, refembling thofe with which Archimedes is faid to have burnt the Roman fleet at the fiege of Syracufe. (See Burning-*Glafs.*) Each of thefe mirrors is about an inch fquare; and they are all arranged clofe to each other in the concave of a parabolic fegment formed of ftucco, which has been found to anfwer the purpofe beft. The idea of thus illuminating light-houfes, inftead of ufing coal-fires, in this country, without any previous knowledge of a fimilar method practifed in France, was firft fuggefted by Mr. Ezekiel Walker, of Lynn Regis, who made, and fixed up reflectors under his direction, in a light-houfe on the coaft of Norfolk, in the year 1779. Accordingly, in the year 1787, at the requeft of the truftees appointed by act of parliament for erecting four light-houfes in the northern parts of Great Britain, he inftructed Mr. Thomas Smith, tin-plate worker, of Edinburgh, to whom the original invention is erroneoufly afcribed in the fupplement to the Encyclopædia Britannica, in this mode of conftructing light-houfes. His parabolic moulds are from three to five or fix feet in diameter; and in the centre or apex of each is placed a long fhallow lamp of tin-plate, filled with whale-oil. In each lamp are fix cotton-wicks, almoft contiguous to one another, fo difpofed as to burn without trimming for fix hours. The light of thefe is reflected from each mirror fpread over the concave furface, and is thus multiplied, as it were, by the number of mirrors. The ftucco moulding is covered on the back with tin-plate, from which a tube, immediately over the lamp, proceeds to the roof of the light-room, and ferves as a funnel, through which the fmoke efcapes without fullying the faces of the mirrors. The light room is a cupola or lantern of from eight to twelve fides, compofed entirely of glafs, fixed in caft iron frames or fafhes, and roofed with copper. On circular branches paffing round the infide of this lantern, at about 18 inches from the glafs frames, are placed the reflectors with their lamps, fo as that the concave furfaces of two or three of the reflectors front every point of the compafs, and throw a blaze of light in all directions. In the roof, immediately over the centre of the room, is a hole, through which pafs all the funnels already mentioned, and which ferves likewife to admit frefh air to the lamps. This light-room is firmly fixed on the top of a round tower, fo as to be immoveable by the weather; and the number of the reflectors, and the height of the tower, are lefs or greater according as it is intended that the light fhould be feen at a lefs or a greater diftance. Experience, it is faid, has obviated feveral objections to which light-houfes of this kind were thought to be liable; and it has been found that light-houfes, with lamps and reflectors, are, in every point of view, preferable to thofe with fires burning in the air. They are fupported at a much lefs expence; their light is more brilliant, and feen at a greater diftance, whilft it can never be obfcured by fmoke, or beaten down, on the leefide, by a violent guft of wind; and they may be fo varioufly placed, that one light-houfe cannot be miftaken for another. Befides, the lamps do not need trimming fo often as open fires require fuel, and the man who attends them is never expofed either to cold or wet in the performance of his duty, fo that they are lefs likely to be neglected in ftormy weather than thofe with open fires.

It has been propofed to make the concave furface of the parabola one fpeculum of metal, inftead of covering it over with a number of plain glafs mirrors; or to diminifh the fize of each mirror, if it be thought beft to retain them inftead of introducing the fpeculum. To this propofed alteration it has been objected, that the brighteft metal does not reflect fuch a quantity of light as well foliated clear glafs; and by diminifhing the fize of the mirrors, the number of joinings would be increafed, in each of which fome light is loft, not merely in the feam, but from its being almoft impoffible to foliate glafs perfectly at its edge.

REFLEX, Reflect, in *Painting*, is underftood of thofe places in a picture which are fuppofed to be illuminated by a light reflected from fome other body reprefented in the fame piece.

Or, reflexes may be defined thofe places which, befide the general light that illumines the whole piece, receive fome particular light from their fituation with refpect to fome more illuminated polifhed body, that reflects part of the rays it receives upon them.

Reflexes are fcarcely fenfible, except in the fhadowed parts. The management of the reflexes requires great accuracy and fkill. All reflected light is fuppofed to carry with it part of the colour of the body which reflects it; fo that thofe places which receive this light, muft have their colour mixed or tinged with that colour. But the fame place may receive reflexes from different objects, differently coloured, and thofe again receive reflexes from others. The painter, therefore, muft have a view to every circumftance of the colour, light, and pofition of each figure; he muft confider what effect each has on others, and purfue nature through all the variety of mixtures. See Clair-obscure, and Light.

Reflex *Vifion*, or Reflected *vifion*, is that performed by means of rays reflected from the polifhed furfaces of objects to the eye.

Reflex vifion is the fubject of catoptrics. Under reflex vifion come all the phenomena of fpecula or mirrors of all kinds.

REFLEXIBILITY *of the Rays of Light*, is that property by which they are difpofed to be reflected. See Reflection.

Or, it is their difpofition to be turned back into the fame medium, from any other medium on whofe furface they fall; hence thofe rays are faid to be more or lefs reflexible, which are returned back more or lefs eafily under the fame incidence.

Thus, if light pafs out of glafs into air, and by being inclined more and more to the common furface of the glafs and air, begins at length to be totally reflected by that furface, thofe forts of rays which at like incidences are reflected moft copioufly, or the rays which, by being inclined, begin fooneft to be totally reflected, are the moft reflexible rays.

That rays of light are of different colours, and endued with different degrees of reflexibility, was firft difcovered by fir Ifaac Newton; and is fhewn by the following experiment. Applying a prifm D F E (*Plate* XVII. *Optics*, *fig.* 15.), whofe angles are each 45°, to the aperture C of a darkened room, in fuch manner as that the light is reflected from the bafe in G; the violet rays are feen firft reflected into H G; the other rays continuing ftill refracted in I K. After the violet the blue are all refracted, the green, &c. (See

(See Colour.) Hence it appears, that the differently coloured rays differ in degree of reflexibility.

From the other experiments it appears, that thofe rays which are moft reflexible, are alfo moft refrangible. See Refrangibility.

REFLEXION. See Reflection.

REFLEXITY, a term employed by Mr. Brougham to denote a property of light, which caufes the different rays to be acted upon by bodies, and to begin to be refracted, reflected, inflected, and deflected, at different diftances. This property obferves the fame law with the other optical properties of light; the red ray having moft reflexity, and the violet the leaft. (See Phil. Tranf. for 1797, p. 360.) Mr. Brougham has expreffed this property by the three words, "refrangity," "reflexity," and "flexity;" but the power being the fame, if fuch a property exift, different names feem to be unneceffary.

REFLUX *of the Sea*, the ebbing of the water; or its return from the fhore. It is thus called, as being the oppofite motion to the flood, or flux. See Tide.

REFORM, a re-eftablifhment, or revival of former neglected difcipline; or a correction of fome reigning abufes in it.

The term is much ufed in a monaftic fenfe, for the reducing an order or congregation of religious to the ancient feverity of the rule from which it had gradually fwerved; or even for the improving on the ancient rule and inftitution itfelf, and voluntarily making it more fevere.

In this fenfe the order of St. Bernard is faid to be only a reform of that of St. Benedict.

To Reform, in a *Military Senfe*, is, after fome evolution or manœuvre, to bring a line to its natural order, by aligning it on fome given point. See Battalion.

To Reform, is alfo to reduce a company, regiment, or other body of men, either by difbanding the whole, or only breaking a part, and retaining the reft; or fometimes by incorporating them with other regiments. Hence,

REFORMADO, or Reformed *officer*, one whofe troop or company is fuppreffed in a reform, whilft he is continued either in whole or half-pay, doing duty in the regiment. A reformed captain of foot follows the company, and affifts the ftanding officer as a fecond; but he ftill maintains his degree and precedence.

REFORMATION, Reformatio, the act of reforming, or correcting an error, or abufe, in religion, difcipline, or the like.

The reformation of religion, called, by way of eminence, *the Reformation*, was begun by the elector of Saxony, at the folicitation of Luther, about the beginning of the fixteenth century. See Luther and Lutheranism.

There were many circumftances which concurred at this time to bring about that happy reformation in religion, which refcued one part of Europe from the papal yoke, mitigated its rigour in the other, and produced a revolution in the fentiments of mankind, the greateft as well as the moft beneficial that has happened fince the publication of Chriftianity. How far the fale of indulgences, publifhed by Leo X., contributed to this event, we have already fhewn under the article Luther. We fhall here obferve, that the fame corruptions in the church of Rome which Luther condemned, had been attacked long before his appearance, and the fame opinions which he propagated had been publifhed in different places, and fupported by the fame arguments. Waldus in the 12th century, Wickliffe in the 14th, and Hufs in the 15th, had inveighed againft the errors of Popery with great boldnefs, and confuted them with more ingenuity and learning than could have been expected in thofe illiterate ages in which they flourifhed. But all thefe premature attempts towards a reformation proved abortive. Many powerful caufes contributed to facilitate Luther's progrefs, which either did not exift, or did not operate with full force in their days: the principal of thefe we fhall here enumerate. The long and fcandalous fchifm which divided the church, during the latter part of the 14th, and the beginning of the 15th centuries, had a great effect in diminifhing the veneration with which the world had been accuftomed to view the papal dignity. The proceedings of the councils of Conftance and Bafil fpread this difrefpect for the Romifh fee ftill wider, and by their bold exertion of authority in depofing and electing popes, taught the world that there was in the church a jurifdiction fuperior even to the papal power, which they had long believed to be fupreme. The wound given on that occafion to the papal authority was fcarcely healed, when the pontificates of Alexander VI. and Julius II. both able princes, but deteftable ecclefiaftics, raifed new fcandal in Chriftendom. Befides, many of the dignified clergy, fecular as well as regular, neglected the duties of their office, and indulged themfelves, without referve, in all the vices to which great wealth and idlenefs naturally give birth; and grofs ignorance and low debauchery rendered the inferior clergy as contemptible as the others were odious. So that we find, long before the 16th century, that many authors of reputation give fuch defcription of the diffolute morals of the clergy, as feems almoft incredible in the prefent age. The fcandal of thofe crimes, which very generally prevailed, was greatly increafed by the facility with which fuch as committed them obtained pardon. The exorbitant wealth of the church, the vaft perfonal immunities of ecclefiaftics, and their encroachments on the jurifdiction of the laity, and their various devices to fecure their ufurpations, created much diffatisfaction among the people, and difpofed them to pay particular attention to the invectives of Luther. Befides thefe caufes of his rapid progrefs, we may alfo reckon the invention of the art of printing, about half a century before his time, the revival of learning at the fame period, and the bold fpirit of inquiry which it excited in Europe; fo that many were prepared to embrace his doctrines, who did not really wifh fuccefs to his undertaking. In the writings of Reuchlin, Hutten, and the other revivers of learning in Germany, the corruptions of the church of Rome are cenfured with an acrimony of ftyle little inferior to that of Luther himfelf. The raillery and oblique cenfures of Erafmus in particular, upon the errors of the church, as well as upon the ignorance and vices of the clergy, prepared the way for Luther's invectives and more direct attacks. To all which we may add, that the theological doctrines of Popery were fo repugnant to the fpirit of Chriftianity, and fo deftitute of any foundation in reafon, in the word of God, or in the practice of the church, that this circumftance combined in favouring the progrefs of Luther's opinions, and in weakening the refiftance of his adverfaries.

The rife of the reformation in Switzerland was at leaft as early as in Germany; for Ulric Zuingle had, in the year 1516, begun to explain the fcriptures to the people, and to cenfure, though with great prudence and moderation, the errors of a corrupt church. He had very noble and extenfive ideas of a general reformation, at the time when Luther retained almoft the whole fyftem of Popery, indulgences excepted; and he had actually called in queftion the authority and fupremacy of the pope, before the name of Luther was known in that country. In the year 1524, Nuremberg, Francfort, Hamburgh, and feveral other cities in Germany, of the firft rank, openly embraced the reformed religion, and by the authority of their magiftrates abolifhed

the

the mafs, and the other fuperftitious rites of Popery. The elector of Brandenburgh, Saxony, the marquis of the landgrave of Heffe, the dukes of Brunfwick and Lunenburgh, and prince of Anhalt, became avowed patrons of Luther's opinions, and countenanced the preaching of them among their fubjects. The reformers derived great advantage from the tranfactions of the diet at Nuremberg, which prefented to the pope a catalogue of a hundred grievances, which the empire imputed to the iniquitous dominion of the papal fee. The progrefs of the reformation in Germany was likewife promoted by the proceedings of the diet held at Spire in the years 1526 and 1529. See LUTHER and PROTESTANTS.

During thefe tranfactions in Germany, the dawn of truth arofe upon other nations. The light of the reformation fpread itfelf far and wide; and almoft all the European ftates welcomed its falutary beams, and exulted in the profpect of an approaching deliverance from the yoke of fuperftition and fpiritual defpotifm. Some of the moft confiderable provinces of Europe had already broke their chains, and openly withdrawn themfelves from the difcipline of Rome and the jurifdiction of its pontiff. The reformed religion was propagated in Sweden, foon after Luther's rupture with Rome, by Olaus Petri, one of his difciples, who was countenanced and encouraged by the valiant and public-fpirited prince Guftavus Vafa Ericfon, to whofe firmnefs and magnanimity it was owing, that from the year 1527 the papal empire in Sweden was entirely overturned, and Guftavus declared head of the church. The light of the reformation was alfo received in Denmark fo early as the year 1521, in confequence of the ardent defire difcovered by Chriftian or Chriftiern II., for purpofes of mere ambition, of having his difciples inftructed in the doctrines of Luther. His fucceffor Frederic, duke of Holftein and Silefia, contributed greatly to the progrefs of the reformation, by his fuccefsful attempts in favour of religious liberty, at the affembly of ftates that was held at Odenfee, in the year 1527, when he procured the publication of the famous edict which declared every fubject of Denmark free, either to adhere to the tenets of the church of Rome, or to embrace the doctrine of Luther; that no perfon fhould be molefted on account of his religion; that a royal protection fhould be granted to the Lutherans; and that ecclefiaftics of every order fhould be allowed to marry. But the honour of accomplifhing this glorious work was referved for Chriftiern III. a prince equally diftinguifhed by his piety and prudence. The religious doctrine, difcipline, and worfhip of this kingdom, were fettled according to a plan laid down by Bugenhagius. And the affembly of the ftates at Odenfee, in 1539, gave a folemn fanction to all thefe tranfactions, and thus the work of reformation was brought to perfection in Denmark.

In the fame year the reformation was eftablifhed in every part of Saxony. Upon the death of George, duke of Saxony, who was an inveterate enemy to the reformation, the fucceffion fell to his brother Henry, whofe attachment to the Proteftant religion furpaffed, if poffible, that of his predeceffor to Popery. Henry invited fome Proteftant divines, and among them Luther himfelf, to Leipfic; and by their advice and affiftance, he learned, in a few weeks, the whole fyftem of ancient rites, eftablifhing the full exercife of the Proteftant religion, with the univerfal applaufe of his fubjects, who had long wifhed for this change, which the obftinacy of their former duke had alone prevented. This revolution delivered the Proteftants from the danger to which they were expofed by having an inveterate enemy fettled in the middle of their territories; and their dominions now extended in a great and almoft unbroken line from the fhore of the Baltic to the banks of the Rhine

In France, the aufpicious patronage of Margaret, queen of Navarre, fifter to Francis I., encouraged feveral pious and learned men, whofe religious fentiments were the fame with her own, to propagate the principles of the reformation, and even to erect feveral Proteftant churches in that kingdom. It appears, that, fo early as the year 1523, there were many, and even perfons of rank, and fome of the epifcopal order, who had conceived the utmoft averfion both againft the doctrine and tyranny of Rome. But the wavering and inconfiftent conduct of Francis I. rendered the fituation of the Proteftants in this country always precarious, often diftreffed. Upon the whole, we may obferve, that, before the diet of Augfburg, the doctrine of Luther had made confiderable, though perhaps a fecret, progrefs in Spain, Hungary, Bohemia, Britain, Poland, and the Netherlands, and had, in all thefe countries, many friends, of whom feveral repaired to Wittemberg to improve their knowledge, and enlarge their views under fuch an eminent mafter. At this diet, held in 1530, the Augfburg or Auguftine confeffion was prefented to the emperor Charles V. and after many debates between the friends of liberty and the votaries of Rome, the latter prevailed; and the diet, in compliance with the opinion and remonftrances of Campeggio, the papal nuncio, iffued a decree, condemning moft of the peculiar tenets held by the Proteftants; forbidding any perfon to protect or tolerate thofe who taught them; enjoining a ftrict obfervance of the eftablifhed rites; and prohibiting any farther innovation, under fevere penalties. Thofe who refufed to obey this decree were declared incapable of acting as judges, or of appearing as parties in the imperial chamber, the fupreme court of judicature in the empire. The Proteftants, alarmed at the feverity of the decree, affembled at Smalcald, and concluded a league of mutual defence againft all aggreffors, by which they formed the Proteftant ftates of the empire into one regular body: and they refolved to apply to the kings of England, France, and Denmark, to implore them to affift and patronize this new confederacy. After various negociations between the emperor and the Proteftant princes, terms of pacification were agreed upon at Nuremberg, and ratified folemnly in the diet of Ratifbon, in the year 1532. In this treaty it was ftipulated, that univerfal peace be eftablifhed in Germany, until the meeting of a general council, the convocation of which, within fix months, the emperor fhall endeavour to procure; that no perfon be molefted on account of religion; that a ftop be put to all proceffes begun by the imperial chamber againft Proteftants; and the fentences already paffed to their detriment be declared void. On their part, the Proteftants engaged to affift the emperor with all their forces in refifting the invafion of the Turks. Thus the Proteftants, by their firmnefs, unanimity, and dexterity in availing themfelves of the emperor's fituation, obtained terms which amounted almoft to a toleration of their religion. But neither the emperor nor the pope were difpofed to abide by the unbiaffed fenfe of a general council, affembled, as the Proteftants wifhed, within the limit of the empire, but determined to decide their religious debates by the force of arms. After many evafions and delays, it was propofed, in the year 1545, to affemble a council at Trent, which was vigoroufly oppofed by the Proteftants. The emperor and the pope had mutually agreed to deftroy all who fhould dare to oppofe this council. The meeting of that affembly was to ferve as a fignal for their taking arms; and accordingly its deliberations were fcarcely begun, in the year 1546, when the Proteftants perceived undoubted marks of a formidable union to overwhelm and crufh them by one blow. The fathers, affembled in the council of Trent, promulgated

 their

their decrees; and the Proteftant princes in the diet of Ratifbon protefted againft their authority; and were, in confequence of this, profcribed by the emperor, who raifed an army to reduce them to obedience. Thus commenced the war of Smalcald, which was profecuted with various fuccefs on both fides, till, in the year 1552, Charles was furprifed at Infpruck by Maurice of Saxony, and was conftrained to conclude at Paffau the famous treaty of *pacification*, (which fee,) with the Proteftants, which is confidered by thofe of Germany as the bafis of their religious liberty; and to promife in fix months to affemble a diet, in which all the tumults and diffenfions, that had been occafioned by a variety of fentiments in religious matters, fhould be entirely removed. This diet, though not affembled at the ftipulated time, met, however, at Augfburg, in the year 1555, and terminated thofe deplorable fcenes of bloodfhed, defolation, and difcord, that had fo long afflicted both church and ftate by that *religious peace*, as it is commonly called, which fecured to the Proteftants the free exercife of their religion, and eftablifhed this ineftimable liberty upon the firmeft foundations. For, after various debates, the following memorable acts were paffed; that the Proteftants who followed the confeffion of Augfburg, fhould for the future be confidered as entirely exempted from the jurifdiction of the Roman pontiff, and from the authority and fuperintendance of the bifhops; that they were left at perfect liberty to enact laws for themfelves, relating to their religious fentiments, difcipline, and worfhip; that all the inhabitants of the German empire fhould be allowed to judge for themfelves in religious matters, and to join themfelves to that church whofe doctrine and worfhip they thought the pureft and moft confonant to the fpirit of Chriftianity; and that all thofe, who fhould injure or perfecute any perfon under religious pretexts, and on account of their opinions, fhould be declared, and proceeded againft, as public enemies of the empire, invaders of its liberty, and difturbers of its peace.

In the year 1533, Henry VIII. king of England, who, in the beginning of thefe troubles, had oppofed the doctrine and views of Luther with the utmoft vehemence, partly becaufe he had fpoken with contempt of Thomas Aquinas, the king's favourite author, having fued for a divorce from Catharine of Arragon, his brother's widow, at the court of Rome, for almoft fix years, during which period Clement VII. negociated, promifed, retracted, and concluded nothing, determined to apply to another tribunal for that decree which he had unfuccefsfully folicited at Rome. Cranmer, archbifhop of Canterbury, by a fentence founded on the authority of univerfities, doctors, and rabbies, who had been confulted with refpect to the point, annulled the king's marriage with Catharine; and Anne Boleyn, whofe charms had captivated the king, was acknowledged as queen of England. Clement, apprehenfive left England would revolt from the holy fee, determined to give Henry fuch fatisfaction as might ftill retain him within the bofom of the church. But the violence of the cardinals precipitated him, in 1534, to iffue a bull refcinding Cranmer's fentence, confirming Henry's marriage with Catharine, and declaring him excommunicated, if, within a time fpecified, he did not abandon the wife he had taken, and return to her whom he had deferted. Enraged at this unexpected decree, Henry kept no longer any meafures with the court of Rome; his fubjects feconded his refentment; an act of parliament was paffed, abolifhing the papal power and jurifdiction in England; by another the king was declared fupreme head of the church, and all the authority of which the popes were deprived was vefted in him; the *monafteries*, (which fee,) were fuppreffed, and their revenues applied to other purpofes.

The people had been gradually prepared for this great innovation. Each fucceeding feffion of parliament had made fome retrenchment from the power and profits of the Roman pontiff. Care had been taken, during fome years, to teach the nation that a general council was much fuperior to a pope. But now a bifhop preached every Sunday at Paul's Crofs, in order to inculcate the doctrine, that the pope was intitled to no authority at all beyond his own diocefe.

The laws paffed during this feffion (1534) fufficiently evince, that the king was determined not to furrender any part of his affumed prerogative. All payments made to the apoftolic chamber: all provifions, bulls, difpenfations, were abolifhed: monafteries were to be fubjected to the regulation and government of the king alone: the law for punifhing heretics was moderated: the ordinary was prohibited from imprifoning or trying any perfon upon fufpicion alone, without prefentment by ten lawful witneffes: and it was declared that to fpeak againft the pope's authority was no herefy: bifhops were to be appointed by a *congé d'elire* from the crown, or, in cafe of the dean and chapter's refufal, by letters patent; and no recourfe was to be had to Rome for palls, bulls, or provifions. Campeggio and Ghinucci, two Italians, were deprived of the bifhoprics of Salifbury and Worcefter, which they had hitherto enjoyed: the law which had been formerly made againft paying annats, or firft fruits, but which had been left in the king's power to fufpend or enforce, was finally eftablifhed: and a fubmiffion which was exacted two years before from the clergy, and which had been obtained with great difficulty, received this feffion the fanction of parliament. In this fubmiffion, the clergy acknowledged that convocations ought to be affembled by the king's authority only: they promifed to enact no new canons without his confent: and they agreed that he fhould appoint 32 commiffioners, in order to examine the old canons, and abrogate fuch as fhould be found prejudicial to his royal prerogative. An appeal was alfo allowed from the bifhop's court to the king in chancery. But the moft important act paffed this feffion, was that which regulated the fucceffion to the crown: the marriage of the king with Catharine was declared unlawful, void, and of no effect: the primate's fentence annulling it was ratified; and the marriage with queen Anne was eftablifhed and confirmed. The crown was appointed to defcend to the iffue of this marriage, and failing there, to the king's heirs for ever. An oath was likewife enjoined to be taken in favour of this order of fucceffion, under the penalty of imprifonment during the king's pleafure, and forfeiture of goods and chattels: and all flander againft the king, queen, or their iffue, was fubjected to the penalty of mifprifion of treafon. Thefe feveral acts, fo contemptuous towards the pope, and fo deftructive of his authority, were paffed at the very time that Clement pronounced his hafty fentence againft the king. The king found his ecclefiaftical fubjects as compliant as the laity. The convocation ordered that the act againft appeals to Rome, together with the king's appeal from the pope to a general council, fhould be affixed to all the doors of all the churches in the kingdom; and they voted that the bifhop of Rome had, by the laws of God, no more jurifdiction in England than any other foreign bifhop; and that the authority which he and his predeceffors had there exercifed, was only by ufurpation, and by the fufferance of Englifh princes. The bifhops went fo far in their complaifance, that they took out new commiffions from the crown, in which all their fpiritual and epifcopal authority was exprefsly affirmed to be derived ultimately from the civil magiftrate, and to be entirely dependent on his good pleafure.

Henry,

Henry, however, with the caprice peculiar to his character, continued to defend the doctrines of the Romish church as fiercely as he attacked their jurisdiction. He alternately persecuted the Protestants for rejecting the former, and the Catholics for acknowledging the latter.

Nothing more forwarded the first progress of the reformers, than the offer which they made, of submitting all religious doctrines to private judgment, and the summons given every one to examine the principles formerly imposed upon them. And what can be more just and reasonable? and yet the multitude, says Mr. Hume, were totally unqualified for this undertaking, though they were highly pleased with it. They fancied that they were exercising their judgment, while they opposed to the prejudices of ancient authority more powerful prejudices of another kind. The novelty itself of the doctrines; the pleasure of an imaginary triumph in dispute; the fervent zeal of the reformed preachers; their patience, and even alacrity, in suffering persecution, death, and torments; a disgust at the restraints of the old religion; an indignation against the tyranny and interested spirit of the ecclesiastics:—these motives, says the same historian, whilst, as some may imagine, he is depreciating the principles of the reformation, were prevalent with the people; and by such considerations were men so generally induced, during that age, to throw off the religion of their ancestors. In proportion, says the same author, as the practice of submitting religion to private judgment was acceptable to the people, it appeared, in some respects, dangerous to the rights of sovereigns, and seemed to destroy that implicit obedience on which the authority of the civil magistrate is chiefly founded. When some Englishmen, such were Tindal, Joye, Constantine, and others, retired to Antwerp, through fear of the exertion of the king's authority, they employed themselves in writing English books against the corruptions of the church of Rome; against images, relics, and pilgrims; and they excited the curiosity of men with regard to that question, which is the most important in theology, the terms of acceptance with the Supreme Being. These books, having been secretly conveyed to England, began to make converts every where; but it was a translation of the scriptures by Tindal that was esteemed the most dangerous to the established faith. Against Wolsey, a favourite minister of Henry VIII., it was one article of impeachment, that, by his connivance, he had encouraged the growth of heresy, and that he had protected and acquitted some notorious offenders. Wolsey was succeeded in the office of chancellor by sir Thomas More, who, irritated by polemics, became so superstitiously attached to the ancient faith, that few inquisitors have been guilty of greater violence in their prosecution of heresy. Several persons were not only brought into the courts for heretical offences, such as teaching their children the Lord's prayer in English, for reading the New Testament in that language, or for speaking against pilgrimages; and others were charged with the capital offences of harbouring persecuted preachers, neglecting the fasts of the church, and declaiming against the vices of the clergy. Some were tried, condemned, and committed to the flames. Notwithstanding the inconsistent conduct of Henry, his subjects having been encouraged, by his example, to break some of their fetters, were so impatient to shake off all that remained, that in the following reign, under his son Edward VI., with the general applause of the nation, a total separation was made from the church of Rome in articles of doctrine, as well as in matters of discipline and jurisdiction. (See Articles.) In 1553, his death retarded the progress of the reformation; and his sister Mary, who succeeded him, imposed a-new the arbitrary laws and tyrannical yoke of Rome upon the people of England. But the execution of a great number of persons, who were burnt for the Protestant faith in the five years of her persecuting and bloody reign, so alienated the people from Popery, that queen Elizabeth, her sister, found it no hard matter to deliver her subjects from the bondage of Rome, and to establish that form of religious doctrine and ecclesiastical government, which still subsists in England.

The seeds of the reformation were very early sown in Scotland, by several noblemen of that nation, who had resided in Germany during the religious disputes that divided the empire. The first and most eminent opposer of the Papal jurisdiction was John Knox, a disciple of Calvin, who set out from Geneva for Scotland in 1559, and in a little while prevailed with the greatest part of the Scotch nation entirely to abandon the superstitions of Rome, and to aim at nothing less than the total extirpation of Popery. In the following year, *viz.* 1560, the parliament ratified a confession of faith, agreeable to the new doctrines, and passing a statute against the mass, not only abolished it in all the churches, but enacted, that whoever, any where, either officiated in it, or was present at it, should be chastised, for the first offence, with confiscation of goods, and corporal punishment, at the discretion of the magistrate; for the second, with banishment; and for the third, with loss of life. A law was also voted for abolishing the Papal jurisdiction in Scotland; the Presbyterian form of discipline was settled, leaving only at first some shadow of authority to certain ecclesiastics, whom they called superintendants. From that period to the present times the form of doctrine, worship, and discipline, that had been established at Geneva by the ministry of Calvin, has been maintained in Scotland with invincible obstinacy and zeal; and every attempt to introduce, into that kingdom, the rites and government of the church of England, has proved impotent and unsuccessful. See Presbyterians.

The cause of the reformation in Ireland underwent the same vicissitudes that had attended it in England. When Henry VIII., after the abolition of the Papal authority, was declared supreme head of the church of England, George Brown, a native of England, and a monk of the Augustin order, whom that monarch had created, in the year 1535, archbishop of Dublin, began to act with the utmost vigour, in consequence of this change in the hierarchy. He purged the churches of his diocese from superstition in all its forms, pulled down images, destroyed relics, abolished absurd and idolatrous rites, and, by the influence as well as authority he had in Ireland, caused the king's supremacy to be acknowledged in that nation. Henry shewed soon after, that this supremacy was not a vain title; for he banished the monks out of that kingdom, confiscated their revenues, and destroyed their convents. In the reign of Edward VI. farther progress was made in the reformation, but the accession of Mary retarded it, in consequence of which Brown and other Protestant bishops were deprived of their dignities in the church. When Elizabeth ascended the throne, the Irish were again obliged to submit to the form of worship and discipline established in England.

The reformation had not been long established in Britain, when the Belgic provinces, united by a respectable confederacy which still subsists, withdrew from their spiritual allegiance to the Roman pontiff. The means which Philip II. king of Spain used to obstruct the reformation, promoted it: the nobility formed themselves into an association, in the year 1566, and roused the people; who, under the heroic conduct of William of Nassau, prince of Orange, seconded by the succours of England and France, delivered this state from

from the Spanish yoke: in consequence of which the reformed religion, as it was professed in Switzerland, was established in the United Provinces; and, at the same time, an universal toleration granted to those whose religious sentiments were of a different nature, whether they retained the faith of Rome, or embraced the reformation in another form, provided that they made no attempts against the authority of the government, or the tranquillity of the public.

Whilst Mr. Hume attributes the quick and surprising progress of the reformation in part to the late invention of printing, and revival of learning, he denies that reason had any considerable share in opening men's eyes with regard to the impostures of the Romish church; alleging that philosophy had made little progress, at least not till long after the period of the reformation, and that no instance occurs in which argument has ever been able to free the people from that enormous load of absurdity with which superstition has every where overwhelmed them: to which he adds, that the rapid advance of the Lutheran doctrine, and the violence with which it was embraced, prove sufficiently that it owed not its success to reason and reflection. The art of printing, and the revival of learning, he says, forwarded its progress in another manner. By means of that art, the books of Luther and his sectaries, full of vehemence, declamation, and a rude eloquence, were propagated more quickly, and in greater numbers. The minds of men, somewhat awakened from a profound sleep of so many centuries, were prepared for every novelty, and scrupled less to tread in any unusual path which was opened to them. And as copies of the scriptures, and other ancient monuments of the Christian faith, became more common, men perceived the innovations which were introduced after the first century; and though argument and reasoning could not give conviction, an historical fact, well supported, was able to make impression on their understandings. As the ecclesiastics would not agree to possess their privileges, though ancient and prior to almost every political establishment in Europe, as matters of civil right, which time might render valid, but appealed still to a divine right, they thus tempted men to look to their primitive charter, which, with little difficulty, they could perceive to be defective in truth and authenticity. Besides, Luther and his followers, not satisfied with opposing the pretended divinity of the Romish church, and displaying the temporal inconveniences of that establishment, proceeded to treat the religion of their ancestors as abominable, detestable, and damnable; foretold by sacred writ itself as the source of all wickedness and pollution. They denominated the pope antichrist, called his communion the scarlet whore, and gave to Rome the appellation of Babylon; expressions which, however applied, were to be found in scripture, and which were better calculated to operate on the multitude than the most solid arguments. Excited by contest and persecution on the one hand, by success and applause on the other, many of the reformers carried to the greatest extremities their opposition to the church of Rome; and in contradiction to the multiplied superstitions with which that communion was loaded, they adopted an enthusiastic strain of devotion, which admitted of no observances, rites, or ceremonies, but placed all merit in a mysterious species of faith, in inward vision, rapture, and ecstacy. The new sectaries, seized with this spirit, were indefatigable in the propagation of their doctrine, and set at defiance all the anathemas and punishments with which the Roman pontiff endeavoured to overwhelm them.

Thus, in terms which appear to us too disparaging, does our historian describe the origin and progress of the reformation; nor does he pay due respect to the principles on which it was founded, and to the character of the persons who were the principal agents in accomplishing it. We are ready to acknowledge, that the collateral circumstances above recited rendered its advances more rapid and more extensive; but we cannot allow that it did not owe much of its success to reason and reflection. But whatever may be our opinion of the primary causes that produced it, its influence on the minds and manners of mankind, on the state of society in general, and on the interests of liberty, religion, and virtue, has been eminently and extensively beneficial. Luther had no sooner began to attack the papal supremacy, than the charm, which had bound mankind for so many ages, was broken at once. The human mind, which had long continued as tame and passive, as if it had been taught to believe whatever was taught, and to bear whatever was imposed, roused of a sudden, and became inquisitive, mutinous, and disdainful of the yoke to which it had hitherto submitted. The reformation, wherever it was received, increased that bold and innovating spirit to which it owed its birth. Men who had the courage to overturn a system, supported by every thing which can command respect or reverence, were not to be overawed by any authority, how great or venerable soever. After having been accustomed to consider themselves as judges of the most important doctrines in religion, to examine these freely, and to reject, without scruple, what appeared to them erroneous, it was natural for them to turn the same daring and inquisitive eye to government, and to think of rectifying whatever disorders or imperfections were discovered there. As religious abuses had been reformed in several places, without the permission of the magistrate, it was an easy transition to attempt the redress of political grievances in the same manner. But though the spirit of innovation, that was excited and promoted by the reformation, might in some instances prove the occasion of turbulence and tumult, the good that eventually accrued from its operation far exceeded the partial and temporary evil that resulted from it. The prevalence of this spirit was so general, that it must have been excited by causes that were natural, and of powerful efficacy; and the consequences that flowed from them must have been as important and interesting as the causes that produced them. The kingdoms of Denmark, Sweden, England, and Scotland, and almost one half of Germany, threw off their allegiance to the pope, abolished his jurisdiction within their territories, and gave the sanction of law to modes of discipline and systems of doctrine, which were not only independent of his power, but hostile to it. Nor was this spirit of innovation confined to those countries which openly revolted from the pope; it spread through all Europe, and broke out in every part of it with various degrees of violence. It penetrated early into France, and made such rapid progress, that the number of converts to the opinions of the reformers was so great, their zeal so enterprising, and the abilities of their leaders so distinguished, that they soon ventured to contend for superiority with the established church, and were sometimes on the point of obtaining it. In all the provinces of Germany which continued to acknowledge the papal supremacy, as well as in the Low Countries, the Protestant doctrines were secretly taught, and had gained so many proselytes, that they were ripe for revolt, and were restrained merely by the dread of their rulers from imitating the example of their neighbours, and asserting their independence: hence in Spain and Italy, symptoms of the same disposition to shake off the yoke appeared. The pretensions of the pope to infallible knowledge and supreme power were treated by many persons of eminent learning and abilities with such scorn, or impugned

with

with ſuch vehemence, that the moſt vigilant attention of the civil magiſtrate, the higheſt ſtrains of pontifical authority, and all the rigour of the inquiſitorial juriſdiction, were requiſite to check or extinguiſh it. The defection of ſo many opulent and powerful kingdoms from the papal ſee was a fatal blow to its grandeur and power, and produced a very conſiderable diminution of its revenues. It likewiſe obliged the Roman pontiffs to adopt a different ſyſtem of conduct towards the nations which continued to recognize their juriſdiction, and to govern them by new maxims, and with a milder ſpirit. They became afraid of venturing upon any ſuch exertion of their authority as might alarm or exaſperate their ſubjects, and excite them to a new revolt. Hence it happens, that the popes, from the era of the reformation, have ruled rather by addreſs and management than by authority. They have been obliged not only to accommodate themſelves to the notions of their adherents, but to pay ſome regard to the prejudices of their enemies. In proceſs of time, and before the convulſions which have lately agitated Europe, they ſunk almoſt to a level with the other petty princes of Italy; and they hardly retain any ſhadow of the temporal power which they anciently poſſeſſed. Neverthelefs, whilſt the reformation has been fatal to the power of the popes, it has contributed to improve the church of Rome both in ſcience and in morals. Many motives have ariſen out of the reformation, and the exiſtence of two rival churches, which have ſerved to engage the Catholic clergy to apply themſelves to the ſtudy of uſeful ſcience, and to pay a ſtrict attention to the manners of their clergy. In thoſe countries where the members of the two churches have mingled freely with each other, or have carried on any conſiderable intercourſe, either commercial or literary, an extraordinary alteration in the ideas, as well as in the morals, of the Popiſh eccleſiaſtics is manifeſt. The beneficial influence of the reformation has not only been felt by the clergy, and the inferior members of the Roman Catholic church; but it has extended to the ſee of Rome, and to the ſovereign pontiffs themſelves, whoſe character, at a later period, has been very different from that of ſeveral of their predeceſſors. Many of them have been conſpicuous for the virtues becoming their high ſtation; and by their humanity, their love of literature, and their moderation, have made ſome atonement to mankind for the crimes of thoſe who in former times occupied their places. Thus the reformation has eminently contributed to increaſe purity of manners, to diffuſe ſcience, and to inſpire humanity. With the progreſs of the reformation we may alſo connect a variety of other important benefits, both to individuals and to ſociety; and as they pertain to the inveſtigation of truth and the improvement of ſcience, to the promotion of liberty both civil and religious, to the diffuſion of knowledge and virtue, and to the advancement of the beſt intereſts of mankind. But the details of the advantages reſulting from the reformation to nations and private perſons, to religion in general, and genuine Chriſtianity in particular, would far exceed the limits to which we are confined.

See, on the ſubject of this article, Robertſon's Hiſt. of Charles V. vol. ii. p. 113, &c. vol. iii. p. 44, &c. Moſheim's Eccl. Hiſt. Eng. ed. 8vo. vol. iii. Burnet's Hiſt. of the Reformation, paſſim. For a comprehenſive, and, upon the whole, a juſt ſketch of the prediſpoſing cauſes, and beneficial conſequences of the reformation, we refer the reader to a work which obtained the prize propoſed by the National Inſtitute of France, 15th of Germinal, in the year X. *viz.* "What has been the influence of the reformation by Luther on the political ſituation of the different ſtates of Europe, and on the progreſs of knowledge?" The work is entitled "An Eſſay on the Spirit and Influence of the Reformation by Luther," by C. Villers. We have two Engliſh tranſlations, one by B. Lambert, and the other by James Mill, 8vo. 1805.

Reformation, *Right of*, *Jus reformationis*, is a right which the princes of Germany claim to reform the church in their reſpective territories; as being inveſted with the ſpiritual as well as the temporal power.

The *jus reformationis* is annexed to the ſovereignty; by this they have the power of conſcience, the diſpoſition of eccleſiaſtical revenues, &c. as they enjoyed the ſame at the treaty of Munſter in 1624.

REFRACTED Angle, in *Optics*, the angle contained between the refracted ray and the perpendicular.

Refracted *Dials*, are ſuch as ſhew the hour by means of ſome refracting tranſparent fluid. See Dials, *Refracted*.

Refracted *Ray*, or *ray of refraction*. See Ray and Refraction.

Refracted *Viſion*. See Vision.

REFRACTING Telescope. See Telescope.

REFRACTION, Refractio, in *Mechanics*, the deviation of a moving body from its direct courſe, by reaſon of the different denſity of the medium it moves in; or a flexion and change of determination, occaſioned by a body's falling obliquely out of one medium into another of a different denſity.

Thus a ball A (*Plate* XXXVI. *Mechanics*, *fig.* 14.) moving in the air in the line A B, and falling obliquely on the ſurface of the water C D, does not proceed ſtraight to E, but deviates, or is inflected, to F. Again, if the ball, moving in water in the ſame line A B, ſhould fall obliquely on a ſurface of air C D; it will not proceed ſtraight to E, nor yet deflect to F, but to G. Now the deflection in each caſe is called the *refraction:* and the two caſes are diſtinguiſhed by means of the perpendicular M I; that B G being called *refraction towards the perpendicular*, or to the *axis of refraction;* and the other B F, *refraction from the perpendicular*, or *from the axis of refraction*.

Theſe refractions are ſuppoſed to ariſe hence, that the ball arriving at B, in the firſt caſe finds more reſiſtance or oppoſition on the one ſide O, *i. e.* from the ſide of the water, than it did from the ſide P, or that of the air; and in the latter more reſiſtance from the ſide P, which is now the ſide of the water, than the ſide O, which is that of the air.

The great law of refraction, then, which holds in all bodies, and all mediums, is that a body, paſſing obliquely out of a medium which reſiſts it more, is refracted towards the perpendicular; and in paſſing out of a medium which oppoſes it leſs into another which oppoſes it more, it is refracted from the perpendicular.

Hence the rays of light falling out of air into water are refracted towards the perpendicular; whereas a ball thrown into the water is refracted from it; becauſe water, which reſiſts the motion of light leſs than air, reſiſts that of the ball more; or, to ſpeak more juſtly, becauſe water, by its greater attraction, accelerates the motion of the rays of light more than air does; for that this is the true cauſe of refraction, at leaſt in light, ſhall be ſhewn under Refraction *of light*.

To have a body refracted, it is neceſſary that it ſhould fall obliquely on the ſecond medium. In perpendicular incidence there is no refraction.

Voſſius

Vossius indeed, and Snellius, imagined they had observed a perpendicular ray of light undergo a refraction; a perpendicular object appearing in the water nearer than in reality it was; but this was to attribute that to a refraction of the perpendicular rays, which was owing to the divergency of the oblique rays after refraction, from a nearer point.

Yet there is a manifest refraction even of perpendicular rays found in *Island* CRYSTAL, which see.

Rohault adds, that though an oblique incidence be necessary in all other mediums we know of, yet the oblique must not exceed a certain degree; if it do, the body will not penetrate the medium, but will be reflected instead of being refracted.

Thus cannon-balls, in sea-engagements, falling very obliquely on the surface of the water, are observed to mount aloft again, and frequently to sweep the men from off the opposite decks; and the like happens to the little stones with which children make their ducks and drakes.

The ancients confounded refraction with reflection, and it was sir Isaac Newton who first taught us the just difference between them. He shews likewise, that there is a good deal of analogy between them, and particularly in the case of light.

The laws of refraction of the rays of light in mediums differently terminated, *i. e.* whose surfaces are plain, concave, convex, &c. make the subject of *dioptrics*; which see.

By refraction it is, that convex glasses, or lenses, collect the rays, magnify objects, burn, &c. and hence the foundation of microscopes, telescopes, &c.

By refraction it is, that all remote objects are seen out of their real places; particularly, that the heavenly bodies are apparently higher than they are in reality, &c.

The refraction of the air has many times so uncertain an influence on the places of celestial objects, very remote from the zenith, that wherever refraction is concerned, the conclusions deduced from observations that are much affected by it, will always remain doubtful, and too precarious in many cases to be relied upon. See Dr. Bradley, in Phil. Transf. N° 485. See *Atmospherical* REFRACTION.

REFRACTION *of Light*, in *Optics*, is an inflection or deviation of the rays from their rectilinear course upon falling obliquely out of one medium into another, of a different density.

The term refraction is derived from the distortion which it occasions in the appearance of an object viewed in part only by refracted light; thus, an oar, partially immersed in water, appears to be bent, on account of the refraction of the light, by which its lower part is seen, in its passage out of the water into the air.

Although no sensible light can penetrate more than 700 feet deep into the sea, and a length of seven feet of water has been found to intercept one-half of the light which enters into it; yet in transparent substances (no medium being, strictly speaking, absolutely transparent) the greater part of the light penetrates to all distances with little interruption, and all rays, of the same kind, thus transmitted by the same surface, form with the perpendicular an angle of refraction, which is ultimately in a certain constant proportion to the angle of incidence; that is, for instance, one-half, three-fourths, or two-thirds, according to the nature of the surface. Thus, if the refractive properties of the substance were such, that an incident ray, making an angle of one degree with the perpendicular, would be so refracted as to make an angle of only half a degree with the same line, another ray, incident at an angle of two degrees, would be refracted, without sensible error, into an angle of one degree. But when the angles are larger, they vary from this ratio, their sines only preserving the proportion with accuracy: for example, if the angle of incidence at the supposed surface were increased to 90°, the angle of refraction would be 30° only, instead of 45°.

It does not appear that, before Descartes, any person attempted to explain the physical cause of the refraction, and also the reflection of light, which he undertook to do by the resolution of forces, on the principles of mechanics; in consequence of which he was obliged to suppose that light passes with more ease through a dense medium than a rare one: thus the ray A B (*Plate* XVIII. *Optics*, *fig.* 10.) falling obliquely on a denser medium at B, is supposed to be acted on by two forces, one of them impelling it in the direction A C, and the other in A D, which alone can be affected by the change of medium: and since, after the ray has entered the denser medium, it approaches the perpendicular B H, it is plain that this force must have received an increase, whilst the other continued the same; for if B E be taken equal to B D, or C A, the consequence of the angle I B H being less than A B C will be, that B H must be longer than B C or A D.

The first person who questioned the truth of this explanation of the cause of refraction was M. Fermat, who asserted, contrary to Descartes, that light suffers greater resistance in water than in air, and greater in glass than in water; and he maintained that the resistance of different mediums, with respect to light, is in proportion to their densities. M. Leibnitz adopted the same general idea; and they reasoned upon the subject in the following manner. Nature, they say, accomplishes her ends by the shortest methods; light, therefore, ought to pass from one point to another, either by the shortest road, or that in which the least time is required. But it is plain that the line in which light passes, when it falls obliquely upon a denser medium, is not the most direct or the shortest; so that it must be that in which the least time is spent. And, whereas it is demonstrable, that light falling obliquely upon a denser medium (in order to take up the least time possible, in passing from a point in one medium to a point in the other), must be refracted in such a manner, that the sines of the angles of incidence and refraction must be to one another, as the different facilities with which light is transmitted in those mediums; it follows that, since light approaches the perpendicular when it passes obliquely from air into water (so that the sine of the angle of refraction is less than that of the angle of incidence), the facility with which water suffers light to pass through it is less than that of the air; so that the light meets with greater resistance in water than in air. This method of arguing from final causes could not satisfy philosophers. Dr. Smith observes that it agrees only to the case of refraction at a plain surface; and that the hypothesis is altogether arbitrary. If he had endeavoured to accommodate his principle to concave and convex surfaces, as he had once proposed, he would soon have perceived its insufficiency. The easiest way for a ray to pass from a given point in any resisting medium into a vacuum, is in a perpendicular to the refracting surface, this being the shortest way, through any difficulty or resistance whatever; but this being reduced to nothing at the refracting surface, it may then take any other course in vacuo, without any farther difficulty; and, on the contrary, in returning back from the vacuum into the dense medium, it must take the shortest course through the same perpendicular as before. Thus, when the sun shines upon the atmosphere, all his rays should be refracted into lines tending to the centre of the earth, as being the shortest and easiest way through the atmosphere, and then we should see the sun exactly over our heads, in all places and at all times. Such is the strange conse-

consequence that follows from an hypothesis so arbitrary.

Dechales, in order to explain the law of refraction, supposes that every ray of light is composed of several smaller rays, which adhere to one another; and that they are refracted towards the perpendicular, in passing into a denser medium, because one part of the ray meets with more resistance than another part; so that the former traverses a smaller space than the latter; in consequence of which the ray must necessarily bend a little towards the perpendicular. This hypothesis was adopted by the famous Dr. Barrow, who, as some say, was the author of it. On this hypothesis, it is plain that mediums of a greater refractive power must give greater resistance to the passage of the rays of light than mediums of a less refractive power, which is contrary to fact.

The Bernouillis, both father and son, have attempted to explain the cause of refraction on mechanical principles; the former on the equilibrium of forces, and the latter on the same principles with the supposition of etherial vortices; but neither of these hypotheses have gained much credit. M. Mairan supposes a subtle fluid, filling the pores of all bodies, and extending, like an atmosphere, to a small distance beyond their surfaces; and then he supposes that the refraction of light is nothing more than a necessary and mechanical effect of the incidence of a small body in those circumstances. There is more, he says, of the refracting fluid in water than in air, less in water than in glass, and in general less in a dense medium than in one that is rarer. M. de Maupertuis supposes that the course which every ray takes, in passing from one medium into another, is that which requires the least quantity of action, which depends upon the velocity of the body, and the space it passes over; so that it is in proportion to the sum of the spaces, multiplied by the velocity with which bodies pass over them. From this principle he deduces the necessity of the sine of the angle of incidence being in a constant proportion to that of refraction: and also all the other laws relating to the propagation and reflection of light.

Dr. Smith (in his Optics, Remarks, p. 70.) observes, that all other theories for explaining the reflection and refractions of light, except sir Isaac Newton's, suppose that it strikes upon bodies, and is resisted by them, which has never been proved by any deduction from experience. On the contrary, it appears by various considerations, and might be shewn by Mr. Molyneux's and professor Bradley's observations on the parallax of the fixed stars, that their rays are not at all impelled by the rapid motion of the earth's atmosphere, nor by the object-glass of the telescope through which they pass. And by sir Isaac Newton's theory of refraction, which is grounded on experience only, it appears, that light is so far from being resisted and retarded by refraction into any dense medium, that it is swifter there than in vacuo, in the ratio of the sine of incidence in vacuo to the sine of refraction into the dense medium. From some cases of the production of colours, we are led to suppose, says Dr. Young (Lect. Phil. vol. i. p. 460.) that the velocity of light must be smaller in a denser than in a rarer medium; and supposing this fact to be established, the existence of such an attractive force as sir Isaac Newton suggests could no longer be allowed; nor, he says, could the system of the emanation of light, in opposition to that of the undulation of an etherial medium, be maintained by any one. Priestley's Hist. of Light, &c. p. 102, &c. p. 333, &c.

The refraction of light, sir Isaac Newton shews, is not performed by the very rays falling on the surface of bodies; but it is done without any contact, by the action of some power belonging to bodies, and extending to a certain distance without their surfaces; by which same power, acting in other circumstances, they are also emitted and reflected.

Admitting that certain powers of attraction and repulsion belong to bodies, and extend to a certain distance beyond their surfaces, and supposing also that light consists of particles emitted from luminous bodies, sir Isaac Newton demonstrates, in his "Principia," that the sine of the angle of incidence must be always to the sine of the angle of refraction in some certain ratio. For, as he proves geometrically, if two similar mediums be separated from each other by a space terminated on both sides by parallel planes, and a body, in its passage through that space, be attracted or impelled perpendicularly towards either of those mediums, and not agitated or hindered by any other force; and if the attraction be every where the same, at equal distances from either plane, taken towards the same hand of the plane, the sine of incidence upon either plane will be to the sine of emergence from the other plane in a given ratio.

In a corollary to this proposition he also shews, that if, instead of one parallel space, bodies be surrounded with several, or an infinite number of them, the attractive power of each of which differs from the next, increasing or decreasing, still, the ratio respecting any two contiguous ones being given, the ratio of the extremes will be given. He also demonstrates, that, if the cause of refraction be the attraction of the refracting medium, the velocity of light before its incidence will be to its velocity afterwards, as the sine of the angle of refraction is to the sine of the angle of incidence; so that light, in passing from a rarer medium into a denser, receives an increase of velocity. The same things being supposed, he shews, that if the velocity before incidence be greater than afterwards, so that the angle of emergence must always increase, in consequence of the repulsive power prevailing over the attractive one, the body will at length be reflected; and that, in this case, the angle of reflection must necessarily be equal to the angle of incidence.

That light does not consist of any mode of action upon a fluid medium, he concludes from having demonstrated that pressure cannot be propagated through a fluid in rectilinear directions, unless where the particles of the fluid lie in a right line, but must diverge into the unmoved spaces; and that every tremulous body, in an elastic medium, propagates the motion of the pulses on every side straight forwards. Admitting this, there is hardly any hypothesis that will agree with the phenomena of light, but that of particles emitted from the luminous body, affected by the attractions and repulsions of other bodies.

The same arguments by which we have proved, that *reflection* (which see) is performed without immediate contact, will go a great way towards demonstrating the same of refraction: to which may be added the following ones.

1. Because, if when light falls out of glass into air with the utmost obliquity it will be transmitted at, it be then made to fall a little more obliquely, it becomes wholly reflected: for the power of the glass, after it has refracted light emerging as obliquely as possible, supposing the rays to fall still more obliquely, will be too strong to let any of the rays pass; consequently, instead of being refracted, they will all be reflected.

2. Because in thin lamellæ, or plates of glass, light is reflected and transmitted several times alternately, as the thickness of the lamellæ increases in arithmetical progression; for here it depends on the thickness of the lamina which of the two the glass shall do, whether reflect it, or let it be transmitted.

3. Because, whereas the power of other bodies both to reflect and refract light are very nearly proportional to their densities;

denfities; yet unctuous and fulphureous bodies are found to reflect more ftrongly than according to their mere denfities; for as the rays act more ftrongly on thofe bodies to kindle them than on others, fo do they again, by their mutual attraction, act more ftrongly on the rays to refract them.

Laftly; Becaufe not only thofe rays tranfmitted through glafs are found to be refracted, but alfo thofe paffing in the air, or in a vacuum near its extremities, or even near the extremes of many opaque bodies, *e. gr.* the edge of a knife, undergo a fimilar inflection, from the attraction of the body. See Light, and alfo Inflection.

The manner in which refraction is performed by mere attraction, without contact, may be thus accounted for: fuppofe H I (*Plate* XVIII. *Optics, fig.* 11.) the boundary of two mediums, N and O; the firft the rarer, *e. gr.* air; the fecond the denfer, *e. gr.* glafs; the attractions of the mediums here will be as their denfities. Suppofe *p* S to be the diftance to which the attracting force of the denfer mediums exerts itfelf within the rarer. Let now a ray of light A *a* fall obliquely on the furface which feparates the mediums, or rather on the furface *p* S, where the action of the fecond and more refifting medium commences. All attraction being performed in lines perpendicular to the attractive body, as the ray arrives at *a*, it will begin to be turned out of its rectilinear courfe by a fuperior force, with which it is attracted by the medium O, more than by the medium N, *i. e.* by a force with which it is driven towards it in a direction perpendicular to its furface: hence the ray is bent out of its right line in every point of its paffage between *p* S and R T, within which diftance the attraction acts. Between thofe lines, therefore, it defcribes a curve *a* B *b*; but beyond R T, being out of the fphere of attraction of the medium N, it will proceed uniformly in a right line, according to the direction of the curve in the point *b*.

Again, fuppofe N the denfer and more refifting medium, O the rarer, and H I the boundary, as before; and let R T be the diftance to which the denfer medium exerts its attractive force within the rarer: even when the ray has paffed the point B, it will be within the fphere of fuperior attraction of the denfer medium; but that attraction acting in lines perpendicular to its furface, the ray will be continually drawn from its ftraight courfe B M perpendicularly towards H I: thus, having two forces or directions, it will have a compound motion, by which, inftead of B M, it will defcribe B *m*, which B *m* will in ftrictnefs be a curve.

Laftly, after it has arrived in *m*, being out of the influence of the medium N, it will perfift uniformly in a right line, in the direction in which the extreme of the curve leaves it.

Thus we fee how refraction is performed, both *towards the perpendicular*, and *from it*.

But note, the attraction of the denfer medium, *e. gr.* N, is continually diminifhing, as the ray proceeds from B, towards the limit of attraction R T; becaufe fewer and fewer parts ftill come to act; at I H, *e. gr.* all the parts between that and *p* S attract; but at R T, none but thofe in the line H I. Note, alfo, that the diftance between *p* S and R T being fmall, when we confider refractions, no notice is taken of the curve part of the ray, but we confider it as confifting of two ftraight lines, C B, A B, or *m* B, A B.

Sir Ifaac Newton, not content with afcribing the reflection, refraction, and inflection of light to powers of attraction and repulfion, extending beyond the furfaces of bodies and producing effect in the manner above explained, propofes a conjecture concerning the phyfical caufe of this attraction and repulfion; but his hypothefis is no lefs liable to difficulties and objections than the hypothefis of the mechanical production of the motion of light without attraction or repulfion. Does not the refraction of light, he fays, arife from the different denfity of an etherial medium in different places, the light always receding from the denfer parts of the medium? And is not the denfity of it greater in free and open fpaces void of air, and other grofs bodies, than within the pores of water, glafs, cryftal, gems, and other compact bodies? For when light paffes through glafs or cryftal, and falling very obliquely upon the farther furface, is all reflected, the total reflection ought to arife rather from the denfity and vigour of the medium without and beyond the glafs, than from the rarity and weaknefs of it.—Does not the etherial medium, in paffing out of water, glafs, cryftal, and other compact and denfe bodies, into empty fpaces, grow denfer and denfer by degrees, and by that means refract the rays of light, not in a point, but by bending them gradually in curve lines? And does not the gradual condenfation of this medium extend to fome diftance from the bodies, and thereby caufe the inflections of the rays of light, which pafs by the edges of the denfe bodies, at fome diftance from the bodies?

Refraction, in *Dioptrics*, is the inflection or bending of the rays of light, in paffing the furfaces of glaffes, lenfes, and other tranfparent bodies of different denfities.

Thus a ray, as A B (*Plate* XVIII. *Optics, fig.* 11.) falling obliquely from the radiant A, upon a point B, in a diaphanous furface, H I, rarer or denfer than the medium along which it was propagated from the radiant; has its direction there altered by the action of the new medium; and inftead of proceeding to M, it deviates, *e. gr.* to C.

This deviation is called the *refraction of the ray;* B C the *refracted ray,* or *line of refraction;* and B the *point of refraction.*

The line A B is called the *line of incidence*, or *ray of incidence;* and, in refpect of it, B is alfo called the *point of incidence.*

The plane in which both the incident and refracted rays are found, is called the *plane of refraction;* a right line B E, drawn in the refracting medium perpendicular to the refracting furface, in the point of refraction B, is called the *axis of refraction:* and a right line D B, drawn perpendicular to the refracting furface, in the point of incidence B, along the medium through which the ray fell, is called the *axis of incidence.*

The angle A B I, included between the incident ray and the refracting furface, is called the *angle of incidence;* and the angle A B D, included between the incident ray and the axis of incidence, is called the *angle of inclination.* The angle M B C, which the refracted ray makes with the incident, is called the *angle of refraction:* and the angle C B E, which the refracted ray makes with the axis of refraction, is called the *refracted angle.*

Refraction, *general laws of.* 1. *A ray of light in its paffage out of a rarer into a denfer medium,* e. gr. *out of air into glafs, is refracted towards the perpendicular,* i. e. *towards the axis of refraction.*

Hence, the refracted angle is lefs than the angle of inclination; and the angle of refraction lefs than that of incidence; as they would be equal were the ray to proceed ftraight from A to M. Hence, alfo, a ray perpendicular to the refracting furface, will pafs through without being refracted, as it cannot be refracted to the perpendicular. The phyfical caufe of which is, that the attraction of the denfer medium, which, in an incidence oblique to its furface acts perpendicularly to that furface, draws the ray out of its courfe: this attraction, we fay, in a perpendicular incidence, acts in the direction of the ray.

2. *The ratio of the fine of the angle of inclination, to the fine*

fine of the refracted angle, is fixed and conftant; viz. if the refraction be out of air into glafs, it is found greater than as 114 to 76, but lefs than 115 to 76; that is, nearly as 3 to 2.

This ratio, affigned by Huygens, agrees with another of fir Ifaac Newton, who makes the fine of the angle of inclination to the fine of the refracted angle, as 31 to 20; which is, likewife, nearly as 3 to 2. Indeed, there is fome difference in the quantity of refraction, in different kinds of glafs; but in phyfical matters, precifenefs is not neceffary. In rain-water, Defcartes found the ratio of the fine of the angle of inclination, to the fine of the refracted angle, as 250 to 187, that is nearly as 4 to 3; which agrees with fir Ifaac Newton's obfervation, who makes it as 529 to 396. In fpirit of wine, the fame great author makes the ratio as 100 to 73; which is not far from the fefquitertian ratio. In air he makes it as 3201 to 3200; and as to air, he fhews, that a ray of light, in traverfing quite through the atmofphere, is refracted the fame as it would be, were it to pafs with the fame obliquity out of a vacuum into air of equal denfity with that in the loweft part of the atmofphere.

See the following table, in which the proportion of the fines which meafure the refractions of feveral bodies; the denfities of the bodies, eftimated by their fpecific gravity; and their refractive power, in refpect of their denfities, are fet down in feparate columns.

The refracting bodies.	The proportion of the fines of incidence and refraction of yellow light.	The denfity and fpecific gravity of the body.	The refractive powerof thebody in refpect of its denfity.

Newton's Optics, edit. 3. p. 247.

M. Euler the younger, purfuing a fcheme fuggefted by his father for afcertaining the refractive powers of tranfparent liquors, made ufe of two Menifeus glaffes, which he put together when they were plunged in the fluid, the refractive power of which he wanted to determine: the edges of thefe glaffes being ground flat, they immediately cohered, fo that none of the fluid could efcape; and then they might both together be wiped, and ufed as one object-glafs in a long tube, which he could lengthen or fhorten at pleafure; and applying an eye-glafs to it, the whole obfervation he had to make was to meafure the exact length of his tube, when he could fee through it moft diftinctly a turret, which was at a confiderable diftance from him. Or, when the focal diftance was lefs than a foot, he only obferved, at what diftance from a wall the image of an oppofite window was the moft diftinct. Ac. Berlin. 1762, p. 302.

The refractive power of the fluids which he examined in this manner, he expreffed in the following tables.

A ray of light paffing from air into	The fine of the angle of incidence will be to that of refraction as ... To unity.

Spirit of turpentine	1.5625	
Amber	1.5556	
A diamond	2.4390	

See Prieftley's Hift. of Light, &c. p. 479, &c.

Whence the different refractive power in different fluids arifes, is not determined. Sir Ifaac Newton fhews, that in many bodies, *e. gr.* glafs cryftal, a felenites, pfeudo-topaz, &c. the refractive power is proportionable to their denfities; only in fulphureous bodies, as camphor, linfeed oil, olive, amber, fpirit of turpentine &c. the power is two or three times greater than in other bodies of equal denfity; yet even thefe have the refractive power with refpect to each other nearly as their denfities.

Water has a refractive power in a middle degree between thofe two kinds of fubftances, and is, probably, of a middle nature. Salts and vitriols have refractive powers in a middle degree between thofe of earthy fubftances and water, and accordingly are compofed of thofe two forts of fubftances. Spirit of wine has a refractive power in a middle degree between thofe of water and oily fubftances; and accordingly feems to be compofed of both, united by fermentation. It appears, therefore, that all bodies feem to have their refractive powers proportional to their denfities, or very nearly, excepting fo far as they partake of more or lefs fulphureous oily particles, and thereby have their refractive powers made greater or lefs. Whence it feems reafonable to attribute the refractive power of all bodies

bodies chiefly, if not wholly, to the fulphureous parts with which they abound.

From the obfervations of M. Euler it appears, that there is no fluid, and probably no tranfparent fubftance of any kind, the refractive power of which is lefs than that of rain-water, or diftilled water; and betwixt air and rain-water there is no fubftance that has an intermediate refractive power.

After rain-water immediately follows well-water; but there are probably as many varieties in its refractive power as there are different wells. We may, however, conclude, that the ratio of refraction from air into well-water is contained between the limits of 1.336 to 1, and 1.337 to 1.

Spirituous liquors have a greater refractive power in proportion to their ftrength: but the ratio of refraction from air into any fpirituous liquor is never lefs than 1.34, nor greater than 1.37.

There is, probably, no kind of falt, but what, being diffolved in water, increafes its refractive power.

The folutions of falt of urine and of vitriol have the leaft refractive powers, and thofe of rock-falt and fal ammoniac the greateft; but the ratio of refraction from air into any faline folution, preferving the proportion of one ounce of falt to twelve of water, will be contained between the limits of 1.34 to 1, and 1.35 to 1.

Diftilled vinegar, and the folution of gum arabic, have nearly the fame refractive power with common French wine; and the refractive power of white of egg is the fame as that of rectified fpirit of wine.

Mineral alkali faturated, feems to have the fame refractive power with very ftrong brandy.

Spirit of nitre and oil of tartar per deliquium have a medium refractive power between fpirituous liquors and oils.

The refractive powers of oils approach the neareft to that of glafs, efpecially oil of turpentine, which had the greateft refractive power of all the fluids on which he had made experiments.

Sir Ifaac Newton fufpected that different *degrees of heat* might have fome effect on the refractive power of bodies, but his method of determining the general refraction was not fufficiently accurate to afcertain this circumftance; but happily this method of M. Euler's proved to be well adapted to this purpofe.

From his experiments made for this purpofe, he infers, that the focal diftance of a fingle lens of glafs diminifhes with the heat communicated to it; and this diminution of the focal diftance is not owing to the increafe of bulk in the glafs by heat; for the effect of this change is both inconfiderable, and of a contrary nature. There can be no doubt, therefore, but that this alteration in the focal diftance is owing to a change in the refractive power of the glafs itfelf, which, as well as, probably, that of all other tranfparent fubftances, is increafed by heat, and diminifhed by cold.

It may feem furprifing that the focal diftance of a fingle lens fhould decreafe with heat, and yet that of the menifcufes filled with any fluid, fhould increafe with heat; but M. Euler obferves, that it by no means follows from hence, that thefe fluids are affected by heat in a manner different from glafs; and, after computing the effect of every circumftance of this complex experiment, of the two glaffes, and the fluid combined, he concludes, that heat increafes the refractive power of water, and of other fluids, as well as that of glafs.

He farther obferves, that as 66 degrees of heat diminifhed the focal diftance $\frac{1}{65}$th part, 33 degrees ought to have diminifhed it $\frac{1}{130}$th part; whereas the diminution in this cafe was $\frac{1}{97}$th. From hence, fays he, one may perhaps conclude, that when it is very cold, the fame change in the thermometer has a greater effect on the refractive power of the glafs than when it is very hot. But he acknowledges that experiments of this kind are not capable of fo much precifion as one could wifh, and that, perhaps in reality, the 66 degrees made a change of $\frac{1}{60}$th, and the 33 degrees of $\frac{1}{120}$th; but he imagined that a great number of experiments, made in different temperatures of the air, might decide the queftion, efpecially if object-glaffes of a very great focal diftance were made ufe of. Ac. Berl. 1762.

The duke de Chaulnes, not fatisfied with the methods ufed by Newton and others for determining the refractive power of glafs, propofed another mode of doing it, which is very ingenious, and, when well conducted, promifing fuccefs. He formed the glafs into plates, the furfaces of which were truly plane and parallel, and having placed fmall objects on each of them, he found, by means of a compound microfcope, to which he applied the moft exquifite micrometer, the different diftances at which they were diftinctly vifible, and compared them with the thicknefs of the glafs. This, he fays, gives the proportion of the fines of the angles of incidence and refraction in that kind of glafs directly. In this method he afcertained the mean refractive power of 15 kinds of glafs. Ac. Par. 1767. See Prieftley's Hift. of Light, &c. p. 483, &c.

Dr. W. H. Wollafton has propofed a new method of examining refractive as well as difperfive powers, by prifmatic reflection. This method was fuggefted by a confideration of fir Ifaac Newton's prifmatic eye-glafs, the principle of which depends on the reflection of light at the inner furface of a denfe refracting medium.

Since the range of inclination, within which total reflection takes place, depends not only on the denfity of the reflecting prifm, but alfo on the rarity of the medium adjacent to it, the extent of that range varies with the difference of the denfities of the two media. When, therefore, the refractive power of one medium is known, that of any rarer medium may be learned, by examining at what angle a ray of light will be reflected from it.

For inftance, when any object is laid under a prifm of flint-glafs, with air alone interpofed, the internal angle of incidence at which the vifual ray begins to be totally reflected, and at which the object ceafes to be feen by refraction, is about 39° 10′; but when the object has been dipped in water, and brought into contact with the glafs, it continues vifible, by means of the higher refractive power of the water, as far as $57\frac{1}{2}$° of incidence. When any kind of oil, or any refinous cement, is interpofed, this angle is ftill greater, according to the refractive power of the medium employed; and, by cements that refract more ftrongly than the glafs, the object may be feen through the prifm, at whatever angle of incidence it is viewed.

In examining the refractive powers of fluids, or of fufible fubftances, the requifite contact is eafily obtained; but, with folids, which can in few inftances be made to touch to any great extent, this cannot be effected without the interpofition of fome fluid, or cement, of higher refractive power than the medium under examination. Since the furfaces of a ftratum fo interpofed are parallel, it will not effect the total deviation of a ray paffing through it, and may therefore be employed without rifk of any error in confequence.

Thus, refin, or oil of faffafras, interpofed between plate-glafs and any other prifm, will not alter the refult.

If, on the fame prifm, a piece of felenite and another of plate-glafs be cemented near each other, their powers may

be

be compared with the same accuracy as if they were both in absolute contact with it.

For such a mere comparison of any two bodies, a common triangular prism is best adapted; but, for the purpose of actual measurement of refractive powers, Dr. Wollaston has preferred the use of a square prism, because, with a very simple apparatus, it shews the sine of refractive power sought, without the need of any calculation.

Let A (*Plate* XVIII. *Optics, fig.* 12.) be a square or rectangular prism, to which any substance is applied at *b*, and let any ray of light parallel to *cb* be refracted through the prism, in the direction *bde*.

Then, if *ef* and *ed* be taken proportional to the sines that represent the refractive powers of the prism and of air, *fg*, which is intercepted between *f* and the perpendicular *eg*, will be the corresponding sine to represent the refractive power of the medium *b*. For since *edg* (opposite to *ef*) is the angle of refraction, *efg* (opposite to *ed*) must be equal to the angle of incidence *bdh*; and *ef* : *fg* :: *bd* : *dh* :: sine of *cbi* : sine of *hbd*.

All, therefore, that is requisite for determining the refractive power of *b*, is to find the means of measuring the line *fg*. On this principle, the instrument in *fig.* 13 is constructed. On a board, *ab*, is fixed a piece of flat deal *cd*, to which, by a hinge at *d*, is jointed a second piece *de*, 10 inches long, carrying two plane sights at its extremities. At *e* is a second hinge, connecting *ef*, 15.83 inches long; and a third at the other extremity of *ef*, by which *fg* is connected with it. At *i* also is a hinge, uniting the radius *ig* to the middle of *ef*; and then, since *g* moves in a semicircle *egf*, a line joining *e* and *g* would be perpendicular to *fg*.

The piece *cd* has a cavity in the middle of it, so that, when any substance is applied to the middle of the prism P, it may continue to rest horizontally on its extremities. When *ed* has been so elevated, that the yellow rays in the fringe of colours (observable where perfect reflection terminates) are seen through the sights, the point *g*, by means of a vernier which it carries, shews by inspection the length of the sign of refraction sought.

The advantages which this method possesses above the usual mode of examining refractive powers, are greater than they may at first sight appear. The usual practice has been, to form two surfaces of the substance under examination, so inclined to each other that the deviation occasioned by them might be measured. The inclination of these surfaces to each other must also be known; and thence the refractive power might be computed. But, in the method here proposed, it is sufficient to have only one surface, and the result is obtained at once, without computation.

The facility of determining refractive powers is consequently such as to render this property of bodies a very convenient test in many philosophical inquiries.

The following table exhibits a series of substances, arranged according to their refractive powers.

Diamond	2.44
Plumbago	——
Native sulphur (double)	2.04
Glass, consisting of lead 6 and sand 1	1.987
Glass of antimony	1.98
Jargon	1.95
Spinelle ruby	1.812
Arsenic	1.811
Muriate of antimony, variable.	
White sapphire	1.768
Gum dragon	——
Iceland spar, strongest	1.657
Sulphate of barytes (double)	1.646
Balsam of Tolu	1.60
Guaiacum	1.596
Benzoin	——
Flint glass	1.586
Ditto	1.583
Horn	——
Phosphorus	1.579
Mica	——
Opium	——
Amber	1.547
Rock crystal (double)	1.547
Old plate-glass	1.545
Colophony	1.543
Box-wood	——
Bees-wax	1.542
Oil of sassafras	1.536
Red sealing-wax	——
Spermaceti, cold	——
Sugar, after fusion	——
Arseniate of potash	——
Mastic	——
Elemi	——
White wax (cold)	——
Oil of cloves	1.535
Copal	1.535
Anime	1.535
Radcliffe crown-glass	1.533
Pitch	——
Centre of crystalline of fish, and dry crystalline of an ox	1.530
Canada balsam	1.528
Crown glass, common	1.525
Selenite	1.525
Caoutchouc	1.524
Gum lac	——
Dutch plate-glass	1.517
Human cuticle	——
Gum arabic	1.514
Balsam of capivi	1.507
Oil of amber	1.505
English plate-glass	1.504
French plate-glass	1.500
Oil of nutmeg	1.497
Sulphate of potash	1.495
Tallow, cold	1.49
Iceland spar, weakest	1.488
Camphor	1.487
Linseed oil	1.485
Butter, cold	1.480
Essence of lemon	1.476
Oil of turpentine, common	1.476
Oil of turpentine, rectified	1.470
Oil of almonds	——
Oil of olives	1.469
Oil of peppermint	1.468
Oil of lavender	1.467
Tallow, melted	1.460
Alum	1.457
Spermaceti, melted	1.446
Crystalline lens of an ox	1.447
to	1.380
Computed average of ditto	1.430
Sulphuric acid	1.435
Fluor spar	1.433
Nitric acid (sp. gr. 1.48)	1.410

Alcohol

Atmofpheric air (Hauksbee) - -	1.00032

See Phil. Tranf. vol. xcii. for 1802. art. 12. See Dispersion *of Light.*

From the law laid down in the beginning of this article, it follows, that one angle of inclination, and its correfponding refracted angle, being found by obfervation, the refracted angles, correfponding to the feveral other angles of inclination, are eafily computed. Now, Zahnius and Kircher have found, that if the angle of inclination be 70°, the refracted angle will be 38° 50′; on which principle Zahnius has conftructed a table of refractions out of air into glafs, for the feveral degrees of the angle of inclination; a fpecimen of which follows:

Angle of Inclination.	Refracted Angle.			Angle of Refraction.		
°	°	′	″	°	′	″
1	0	40	5	0	19	55
2	1	20	6	0	39	54
3	2	0	3	0	59	56
4	2	40	5	1	19	55
5	3	20	3	1	39	57
10	6	39	16	3	20	44
20	13	11	35	6	48	25
30	19	29	29	10	30	31
45	28	9	19	16	50	41
90	41	51	40	48	8	20

Hence it appears, that if the angle of inclination be lefs than 20°, the angle of refraction out of air into glafs is almoft one-third of the angle of inclination; and, therefore, a ray is refracted to the axis of refraction, by almoft a third part of the quantity of its angle of inclination. And on this principle it is that Kepler, and moft other dioptrical writers, demonftrate the refractions in glaffes; though in eftimating the law of thefe refractions, he followed the example of Alhazen and Vitellio, and fought to difcover it in the proportion of the angles, and not in that of the fines.

The true law of refraction was firft difcovered by Willebrord Snellius, profeffor of mathematics at Leyden; who found by experiment that the fecants of the complements, or co-fecants, of the angles of incidence and refraction, are always in the fame ratio. It is vulgarly attributed, however, to Defcartes; who having feen it in Snellius's MS., firft publifhed it in his Dioptrics, without naming Snellius; as we are informed by Huygens. The form in which Defcartes gives this law is different from that of Snellius, and in general more commodious; but it might have been eafily deduced from it. According to him, the fine of the angle of refraction always bears the fame proportion to the fine of the angle of incidence. Indeed, as the rays of light are not all of the fame degree of refrangibility, this conftant ratio muft be different in different kinds. The ratio, therefore, obferved by authors, is to be underftood of rays of the mean refrangibility, *i.e.* of green rays. The difference of refraction between the leaft and moft refrangible rays, that is, between violet and red rays, fir Ifaac Newton fhews is about the $27\frac{1}{2}$th part of the whole refraction of the mean refrangible; which difference he owns is fo fmall, that there feldom needs to be any regard paid to it.

3. *When a ray paffes out of a denfer into a rarer medium, e. gr. out of glafs into air, it is refracted from the perpendicular, or from the axis of refraction.* And hence the angle of refraction is greater than the angle of inclination.

Hence, alfo, if the angle of inclination be lefs than 30°, M B C (*Plate* XVIII. *Optics, fig.* 11.) is nearly equal to one-third of M B E; therefore M B C is one-half of C B E; confequently, if the refraction be out of glafs into air, and the angle of inclination lefs than 30°, the ray is refracted from the axis of refraction by almoft one-half part of the angle of inclination. And this is the other dioptrical principle ufed by moft authors after Kepler, to demonftrate the refraction of glaffes.

If the refraction be out of air into glafs, the ratio of the fine of inclination to the fine of the refracted angle is as 3 to 2, or, more accurately, as 17 to 11; if out of air into water, as 4 to 3: therefore, if the refraction be the contrary way, *viz.* out of glafs or water into air, the ratio of the fines, in the former cafe, will be as 2 to 3, or 11 to 17, and in the latter as 3 to 4.

Hence, if the refraction be from water or glafs into air, and the angle of incidence or inclination be greater than about $48\frac{1}{2}$° in water, or greater than about 40° in glafs, the ray will not be refracted into air, but will be reflected into a line, which makes the angle of reflection equal to the angle of incidence; becaufe the fines of $48\frac{1}{2}$° and 40° are to the radius as 3 to 4, and as 11 to 17 nearly, and therefore when the fine has a greater proportion to the radius than as above, the ray will not be refracted.

4. *A ray falling on a curve furface, whether concave or convex, is refracted after the fame manner as if it fell on a plane which is a tangent to the curve in the point of incidence.*

For the curve and plane furface touching it, have an infinitely fmall part common to them both (each being originally generated by the flux of a point). But a ray is refracted in fuch a little part; therefore it is the fame as if it were refracted in fuch a plane.

5. *If a right line* E F (*Plate* XVIII. *Optics, fig.* 14.) *cut a refracting furface,* G H, *at right angles; and if, from any point in the denfer medium, as* D, *be drawn* D C *parallel to the incident ray* A B: *this will meet the refracted ray in* C; *and will be to it as the fine of the refracted angle to the fine of the angle of inclination.*

For $o = x$; but if B C pafs out of a denfer medium into a rarer, $y > x$; and out of a rarer into a denfer, $y < x$; therefore, in the former cafe, $y > o$, in the latter $y < o$; confequently, in the former, $o + u < y + u$; in the latter $y + u < o + u$. But in the one cafe $o + u$, and in the other $y + u$, are equal to two right angles; therefore, $o + u$ in this, and $y + u$ in the other, are lefs than two right angles, and confequently D C will meet B C. But fince $o = x$, or the angle of inclination, and y is the refracted angle, it is evident that C B is to C D as the fine of the angle o to the fine of the angle y, or in the ratio of the fine of the angle of inclination to the fine of the refracted angle.

Hence, if B C pafs out of glafs into air, it is in a fubfefquialterate ratio to C D; if, on the other hand, it paffes out of air into glafs, it is in a fefquialterate ratio to C D.

Hence, alfo, if light pafs out of water into air, C B is in a fubfefquitertian ratio to C D; if out of air into water, in a fefquitertian. See *figs.* 14 and 15.

Refraction *in plane furfaces, laws of.* 1. If parallel rays be refracted out of one tranfparent medium into another of a dif-a different denfity, they will continue parallel after refraction. The phyfical reafon is, that, being parallel, their obliquity, or angle of incidence, is the fame; but, at equal obliquities, we have fhewn the refraction is equal; confequently the parallelifm, which they had before the refraction, will be retained after it.

But this may be alfo demonftrated geometrically: thus, if the rays be perpendicular to the refracting furface, they will pafs without any refraction; confequently being parallel before their paffage, they will be fo after it. If they fall obliquely, as A B and C D (*fig.* 16.), the angles of incidence o and u, and, confequently, alfo the angles of inclination x and y, will be equal. But the fines of the angles of inclination x and y have the fame ratio to the fines of the refracted angles m and n; therefore the refracted angles m and n, and alfo the angles s and r, are equal; confequently the refracted rays are parallel.

Hence a glafs, plane on both fide, being turned directly to the fun, the light paffing through it will be propagated after the fame manner as if the glafs were away; for the rays being perpendicular, will pafs without refraction. If the glafs be turned obliquely to the fun, the light, after refraction, will be of the fame intenfity as before, the intenfity depending on the fpiffitude or clofenefs of the rays, and on the angle with which they ftrike the object, or the eye; both which are here unvaried.

2. If two rays D C and C P (*fig.* 17.) proceeding from the fame radiant C, and falling on a plane furface of a different denfity, fo that the points of refraction D and P are equally diftant from the cathetus of incidence G K, the refracted rays D F and P Q have the fame virtual focus, or the fame point of difperfion G.

Hence, 1. Since, in rays very near each other, the diftance from the cathetus is the fame as to fenfe, very near rays will diverge from the fame point G, *i. e.* they will have the fame virtual focus G.

And hence, 2. When refracted rays, falling on the eye placed out of the cathetus of incidence, are either equally diftant from the cathetus, or very near each other, they will flow upon the eye, as if they came to it from the point G; confequently the point C will be feen by the refracted rays as in G.

3. If a ray C D fall obliquely out of a thinner into a denfer medium, having a plane furface, the diftance of the radiant point C K will have a lefs ratio to the diftance of the point of difperfion, or virtual focus, K G, than the fine of the refracted angle to the fine of the angle of inclination. But if the diftance of the point of refraction, from the cathetus of incidence K D, be lefs than the eleventh or nineteenth part of the diftance of the radiant point C K; and if in the former cafe the tenth, and in the latter the hundredth, part of it be fo fmall, that it cannot be affigned, or need not be minded, then will C K be to K G, as to fenfe, in the ratio of the fine of the refracted angle, to the fine of the angle of inclination.

Hence, 1. If the refraction be out of air into glafs, the diftance of the point of difperfion of rays near the cathetus is fefquialterate of the radiant point; of more remote rays greater than fefquialterate. But if the refraction be out of air into water, the diftance of the fame point will be fefquitertian, when the rays are near the cathetus; and when more remote, greater than fefquitertian.

Hence, 2. If the eye be placed in a denfe medium, objects in a rarer will appear more remote than they are; and the place of the image, in any given cafe, may be determined from the ratio of the refraction. *Thus, to fifhes fwimming under water, objects out of the water muft appear farther diftant than in reality they are.*

4. If a ray D G fall obliquely out of a denfer into a rarer medium A B, the diftance of the radiant point G K has a greater ratio to the diftance of the point of difperfion K C, than the fine of the refracted angle has to the fine of the angle of inclination. In the other cafe of the preceding theorem, K G will be to K C, as to fenfe, in the ratio of the fine of the refracted angle, to the fine of the angle of inclination.

Hence, 1. If the refraction be out of glafs into air, the diftance of the point of difperfion of the rays near the cathetus of incidence is fubfefquialterate of the diftance of the radiant point; that of the more remote rays is lefs than fubfefquialterate.

But, 2. If the refraction be out of water into air, the diftance of the point of difperfion of rays near the cathetus is fubfefquitertian; of thofe more remote, lefs than fubfefquitertian.

And, 3. The eye, therefore, being placed in a rarer medium, objects, placed in a denfer, appear nearer than they are; and the place of the image may be determined in any given cafe by the ratio of refraction. Hence, the bottom of a veffel full of water is raifed by refraction to a third part of its height, with refpect to an eye perpendicularly over the refracting furface; and hence *fifhes, and other bodies under water, appear nearer than they really are.*

5. If the eye be placed in a rarer medium, an object feen in a denfer medium, by a ray refracted in a plane furface, will appear larger than it really is. If the object be in a rarer, and the eye in a denfer medium, the object will appear lefs than it is. And, in each cafe, the apparent magnitude is to the real one in a ratio compounded of the diftance of the point to which the rays tend before refraction, from the refracting furface D E (*fig.* 18.) to the diftance of the eye G L from the fame, and of the diftance G M of the object A B from the eye, to its diftance F M from a point F, to which the rays tend before refraction.

Hence, 1. If the object A B be very remote, F M will be phyfically equal to G M; and, therefore, the real magnitude M B is to its apparent one M H, as G L to F L, or the diftance of the eye G from the refracting plane to the diftance of the point of convergence F from the fame plane.

Hence, 2. *Objects under water, to an eye in the air, appear larger than they are; and to fifhes under water, objects in the air appear lefs than they are.*

Refraction, *Laws of, in fpherical furfaces, both concave and convex.* 1. A ray of light D E (*fig.* 19.) parallel to the axis of a denfer fphere, after a fingle refraction in E, falls in with the axis in the point F, beyond the centre C.

For the femidiameter C E, drawn to the point of refraction E, is perpendicular to the furface K L, and is therefore the axis of refraction; but a ray out of a rarer into a denfer medium, we have fhewn, is refracted towards the perpendicular, or the axis of refraction; therefore the ray D E will converge to the axis of the fphere A F; and will, therefore, at length concur with it, and that beyond the centre C, in F; becaufe the angle of refraction F E H is lefs than the angle of inclination C E H.

2. If a ray D E fall on a fpherically convex furface of a denfer medium, parallel to its axis A F; the femidiameter C E will be to the refracted ray E F in the ratio of the fine of the angle of refraction, to the fine of the angle of inclination; but the diftance of the focus, or point of concurrence from the centre C F, is to the refracted ray F E, in the ratio

ratio of the fine of the refracted angle, to the fine of the angle of inclination.

3. If a ray D E fall on a denfer fpherical convex furface K L, parallel to the axis A F, the diftance of the focus from the refracting furface F B muft be to its diftance from the centre F C, in a ratio greater than that of the fine of the angle of inclination, to the fine of the refracted angle. But if the rays be very near the axis, and the angle of inclination B C E be only of a few degrees, the diftances of the focus from the furface, and the centre, F B and F C, will be nearly in the ratio of the fine of the angle of inclination, to the fine of the refracted angle.

Hence, 1. If the refraction be out of air into glafs; in the cafe of rays near the axis, B F : F C :: 3 : 2. And in the cafe of rays remote from the axis, B F : F C > 3 : 2. Confequently, in the former cafe, B C : B F :: 1 : 3; and in the latter, B C : B F < 1 : 3.

And, 2. If the refraction be out of air into water; in the former cafe, B F : F C :: 4 : 3; and in the latter, B F : F C > 4 : 3. Confequently, in the former, B C : B F :: 1 : 4; and in the latter, B C : B F < 1 : 4.

Hence, 3. Since the fun's rays are parallel as to fenfe, if they fall on the furface of a folid glafs fphere, or of a fphere full of water, they will not concur with the axis within the fphere; fo that Vitellio was miftaken, when he imagined, that the fun's rays, falling on the furface of a cryftalline fphere, were refracted to the centre.

4. If a ray D E (*fig.* 20.), parallel to the axis F A, fall out of a denfer into a rarer fpherical medium, after refraction, it will diverge from the axis; and the diftance of the point of difperfion, or the virtual focus from the centre of the fphere F C, will be to its femi-diameter C E in the ratio of the fine of the refracted angle, to the fine of the angle of refraction; but to the portion of the refracted ray drawn back, F E, it will be in the ratio of the fine of the refracted angle, to the fine of the angle of inclination.

5. If a ray E D fall parallel to the axis A F on the fpherically convex furface K L of a rarer medium, out of a denfer, the diftance of the point of difperfion from the centre F C, is to its diftance from the furface F B, in a ratio greater than that of the fine of the refracted angle to the fine of the angle of inclination. But if the rays D E be very near the axis F A, the ratio will be very nearly the fame with that of the fine of the refracted angle to the fine of the angle of inclination.

Hence, 1. If the refraction be out of glafs into air, in the cafe of rays near the axis, F C : F B :: 3 : 2. Confequently B C : F B :: 1 : 2. Therefore, in the cafe of rays more remote from the axis, F C : F B > 3 : 2.

2. If the refraction be out of water into air; in the former cafe F C : F B :: 4 : 3. Confequently, B C : F B :: 1 : 3; in the latter cafe therefore, F C : F B > 4 : 3.

3. Since then the point of difperfion F is more remote from the refracting furface K L, if the rays proceed out of water, than if they pafs out of glafs into air; parallel rays are lefs difperfed in the former cafe than in the latter.

6. If a ray H E (*fig.* 19.) fall parallel to the axis F A, out of a rarer, on the furface of a fpherically concave denfer medium; the refracted ray E N will be driven from the point of the axis F; fo that F E will be to F C in the ratio of the fine of the angle of inclination, to the fine of the refracted angle.

7. If a ray E H fall parallel to the axis F B on the concave furface K L of a fpherical denfer medium, from a rarer; the diftance of the point of difperfion from the refracting furface F B, is to its diftance from the centre F C, in a ratio greater than that of the fine of the angle of inclination, to the fine of the refracted angle. But if the rays be very near the axis, and the angle B C E be very fmall, B F will be to C F very nearly in the ratio of the fine of the angle of inclination, to the fine of the refracted angle.

Hence, 1. If the refraction be out of air into glafs; in the cafe of rays near the axis, F B : F C :: 3 : 2; in the cafe of rays more remote from the axis, F B : F C > 3 : 2; confequently, in the former, B C : F C :: 1 : 2. And hence, in the latter, B C : F C < 1 : 2.

Hence alfo, 2. If the refraction be out of air into water; in the cafe of rays near the axis, F B : F C :: 4 : 3. In the cafe of rays more remote from the axis, F B : F C > 4 : 3; confequently, in the firft cafe, B C : F C :: 1 : 3. And hence, in the latter, B C : F C > 1 : 3.

And hence, 3. Since the point of difperfion F is farther from the centre C, if the refraction be in water than in air; rays will be lefs difperfed in the latter cafe than in the former.

8. If the ray H E (*fig.* 20.) fall parallel to the axis A F, from a denfer upon the furface of a fpherical concave rarer medium, the refracted ray will concur with the axis A F, in the point F; fo that the diftance of the point of concourfe from the centre C F, may be to the refracted ray F E, in the ratio of the fine of the refracted angle, to the fine of the angle of inclination.

9. If a ray H E fall parallel to the axis A F on the concave furface of a rarer medium out of a denfer, the diftance of the focus from the centre F C will be to its diftance from the refracting furface F B in a greater proportion than the fine of the refracted angle, to the fine of the angle of inclination. But if the rays be very near the axis, F C will be to F B in the proportion of thefe fines.

Hence, 1. If the refraction be out of glafs into air; in the cafe of rays near the axis, F C : F B :: 3 : 2; in the cafe of rays more remote from the axis, F C : F B > 3 : 2. Whence, in the former cafe, B C : F B :: 1 : 2.

2. If the refraction be out of water into air; in the cafe of rays near the axis, F C : F B :: 4 : 3; in the cafe of rays more remote, F C : F B > 4 : 3. Whence, in the former cafe, B C : F B :: 1 : 3. For the demonftration of thefe feveral laws of refraction, we refer to Wolfius's Elem. Mathef. &c. tom. iii. p. 179, &c. See alfo Lens.

Refraction *in a glafs prifm.* If a ray of light D E (*fig.* 21.) fall obliquely out of air on a prifm A B C; being refracted towards the perpendicular, inftead of proceeding to F, it will decline to G, *i. e.* towards a line H I, drawn perpendicular to the furface A B in the point of refraction E. Again, fince the ray E G, paffing out of the glafs into air, falls obliquely on C B, it will be refracted to M, fo as to recede from the perpendicular N G O. *And hence arife the various phenomena of the prifm.* See Colour and Refrangibility.

Refraction *in a convex lens.* If parallel rays, A B, C D, and E F (*fig.* 22.) fall on the furface of a lens 2 B 3 K, the perpendicular ray A B will pafs unrefracted to K, where emerging into air perpendicular, as before, it will proceed ftraight to G. But the rays C D and E F, falling obliquely out of air into glafs, in D and F, will be refracted towards the axis of refraction (*i. e.* towards lines H I and L M, drawn perpendicular to the refracting furface in the points of refraction D and F) and decline to Q and P. Again, emerging obliquely out of the glafs into the furface of the air, they will be refracted from the perpendicular, and, therefore, D Q will not proceed to X, but to G; and F P, not to V, but to G; thus, likewife, might all the other rays, falling on the

the furface of the glafs, be fhewn to be refracted fo as to meet the reft about the point G. See Focus and Lens.

Hence the great property of convex glaffes; *viz. that they collect parallel rays, or make them converge into a point.*

Refraction *in a concave lens.* Parallel rays A B, C D, and EF (*fig.* 23.) falling on a concave lens G B H I M K, the ray A B, falling perpendicular on the glafs at B, will pafs unrefracted to M; where being ftill perpendicular, it will pafs into the air without refraction, to L. But the ray C D, falling obliquely on the furface of the glafs, will be refracted towards the perpendicular N D O, and proceed to Q; and the ray D Q, again falling obliquely out of the glafs upon the furface of air, will be refracted from the perpendicular R Q S, and proceed to V. After the fame manner might the ray E F be fhewn to be refracted to Y, and thence to Z.

Hence the great property of concave glaffes; *viz. that they difperfe parallel rays, or make them diverge.* See Lens and Mirror.

Refraction *in a plane glafs.* If parallel rays E F, G H, I L (*fig.* 24.) fall obliquely on a plane glafs A B C D, the obliquity being the fame in all, by reafon of their parallelifm, they will be all equally refracted towards the perpendicular; and accordingly, being ftill parallel at M, O, and Q, they will pafs out into the air equally refracted again from the perpendicular, and ftill parallel.

Thus will the rays E F, G H, and I L, at their entering the glafs, be inflected towards the right; and in their going out as much inflected to the left; fo that the firft refraction is here undone by the fecond: though not fo as that the object is feen in its true place. For the ray B Q, being produced back again, will not coincide with the ray L I, but will fall to the right of it; and this the more as the glafs is thicker; however, as to matter of colour, the fecond refraction does really undo the firft. See Colour.

Refraction *of Heat.* See Heat, Light, and Rays *of Heat.*

Refraction *in Iceland* or *Ifland cryftal.* See *Iceland* Crystal. Dr. Young, who maintains that radiant light confifts in undulations of the luminiferous ether, takes occafion to make fome remarks on fir Ifaac Newton's theory of the peculiar refraction in Iceland cryftal. Newton, he fays, has advanced the fingular refraction of the Iceland cryftal, as an argument that the particles of light muft be projected corpufcles; fince he thinks it probable that the different fides of thefe particles are differently attracted by the cryftal, and fince Huygens has confeffed his inability to account, in a fatisfactory manner, for all the phenomena. But contrarily to what might have been expected from Newton's ufual accuracy and candour, he has laid down a new law for the refraction, without giving a reafon for rejecting that of Huygens, which Mr. Haüy has found to be more accurate than Newton's; and, without attempting to deduce from his own fyftem any explanation of the more univerfal and ftriking effects of doubling fpars, he has omitted to obferve, that Huygens's moft elegant and ingenious theory perfectly accords with thefe general effects, in all particulars, and of courfe derives from them additional pretenfions to truth; this he omits, in order to point out a difficulty for which only a verbal folution can be found in his own theory, and which will probably long remain unexplained by any other.

Dr. Wollafton, in his paper on the oblique refraction of Iceland cryftal, confirms the experiments of Huygens on this fubftance, with additional evidence, deduced from the fuperiority of his mode of examining the powers of refraction. He obferves that Dr. Young has already applied the Huygenian theory with confiderable fuccefs to the explanation of feveral other optical phenomena, and that it appears to be ftrongly fupported by fuch a coincidence of the calculations deduced from it, with the refults of thefe experiments, as could have fcarcely happened to a falfe theory.

In ordinary cafes, the incipient undulations are of a fpherical form; but in the Iceland cryftal light appeared to Huygens to proceed as if the undulations were portions of an oblate fpheroid, of which the axis is parallel to the fhort diagonal of an equilateral piece of the cryftal, and its centre the point of incidence of its ray. From this fpheroidal form of the undulations, he deduces the obliquity of refraction; and lays down a law obfervable in all refractions, at any furface of the fpar, whether natural or artificial, which bears the clofeft analogy to that which obtains, univerfally, at other refractory furfaces; for as, in other cafes, the ratio is given between the fine of incidence and fine of refraction, (or ordinate of the *fpherical* undulation propagated,) fo in the Iceland cryftal, the ratio between the fine of incidence and ordinate of refraction (in any one fection of the *fpheroidical* undulation) in a given ratio, but different in different planes.

Dr. Wollafton obferves, that though we do not fully underftand the exiftence of a double refraction, and are utterly at a lofs to account for the phenomena occurring upon a fecond refraction, by another piece of the fpar, yet that the oblique refraction, when confidered alone, is nearly as well explained as any other optical phenomenon. Phil. Tranf. for 1801 and for 1802.

Refraction, *Particular laws of*, in different kinds of lenfes; fee Lens.

Refraction, *Atmofpherical*, is generally confidered under two diftinct heads; *viz.* aftronomical refraction, which is that relating to the refraction of the moon, ftars, and other celeftial bodies; and terreftrial refraction, or that which takes place in terreftrial obfervations.

It appears, from the article Refraction, that a ray of light is refracted in paffing obliquely out of one medium into another of different denfity; and as the atmofphere may be confidered as compofed of an infinitude of ftrata, whofe denfity increafe as they are pofited nearer the earth, the luminous rays which pafs through it are acted on as if they paffed fucceffively through media of increafing denfity, and are therefore inflected more and more towards the earth, as the denfity augments, that is, as they approach the eye of the obferver. In confequence of this it is, that rays from objects, whether celeftial or terreftrial, proceed in curves which are *concave* towards the earth; and fince the mind always refers the place of objects to the direction in which the rays reach the eye, that is, to the direction of the tangent to the curve at that point, it follows, that the apparent or obferved elevation of objects is always greater than the true one, at leaft with the exception of fome few remarkable anomalies which fometimes, in terreftrial obfervations, produce a contrary effect, and of which we have ftated a few particular inftances under the article Mirage, and on which fubject fome other curious facts are recorded in a memoir of profeffor Vince's, in the Phil. Tranf.; in Nicholfon's Philofophical Journal, 4to.; and more particularly by M. Monge, in vol. i. of the "Decade Egyptienne." Referring the reader therefore to thofe works, to which we ought alfo to add the memoir by M. Biot, in vol. x. of the National Inftitute, for an account and explanation of thofe phenomena, we fhall confine our prefent obfervations to thofe cafes only, in which an uniform law is fuppofed to have place, and which, as we have feen, has a conftant tendency to augment the obferved altitude of both terreftrial and celeftial objects.

objects. In order to submit the phenomena of refraction to strict mathematical investigation, it must be observed that, in consequence of the inconsiderable height of the atmosphere, and its spherical form, a luminous ray impinging upon it, even in the most unfavourable case, that is directly in the horizon, traverses only a small quantity of this medium; and in this space, if the atmosphere is calm, the density of the air at equal heights above the level of the sea is every where the same. Therefore, in supposing the earth spherical, a supposition which may be admitted, in the present case, without any sensible error, we may consider the atmosphere as composed of successive spherical concentric shells, or strata, of which the density diminishes from the surface of the earth upwards.

Let us conceive, now, a luminous ray, coming from a distance, to penetrate into one of the supposed spherical shells; then, if through the common centre of these shells, which is the same as the centre of the earth, we suppose a plane to pass in the direction of the luminous ray, the spherical beds of the atmosphere will be found divided into two equal portions, which acting equally upon the ray, can produce no deviation of it from that plane; whence it follows, that the effect of refraction is entirely produced in a vertical direction, and in such a manner as to augment the apparent altitudes of the heavenly bodies, and consequently to diminish their zenith distances.

But the intensity of these effects will not be the same at all heights, for we know that in all cases the quantity of refraction depends upon the obliquity of incidence, and therefore the refraction in the zenith is equal to zero, and increases from that point to the horizon, where it is the greatest.

If, now, we knew the law by which the density of the air is diminished in ascending from the earth, that is, if we knew the difference in the density of any two consecutive strata, it would be comparatively a direct and easy problem to find the whole amount of refraction for any given angle of observation; but unfortunately the uniformity of decrease in the density of the atmosphere, which, according to theory, is in geometrical progression, is so much interrupted by the multitude of causes which may tend to produce this effect, that it is found that the quantity of refraction computed on this principle, will by no means agree with that deduced from actual observation. It has been, however, demonstrated, that the quantity of refraction, in all cases exceeding 10 or 12 degrees of elevation, is not sensibly affected by any irregularity in the law of density, in the strata of which we have supposed the atmosphere to be composed, but that it depends simply upon its pressure and temperature at the time and place of observation, which are indicated at the time by the barometer and thermometer. It was formerly thought, also, that refraction was influenced by the degree of humidity and dryness of the air; but from a great variety of interesting and accurate experiments, carried on by M. M. Biot and Arrago, it appears indisputably established, that no sensible effect is thence produced. See a memoir on this subject by the former author, in vol. x. of the National Institute.

But before we proceed farther on this interesting subject, it will be proper to give a sketch of the several improvements which the theory has experienced in the hands of different celebrated astronomers; in doing which we shall avail ourselves of a memoir, published by Dr. T. S. Evans in the Philosophical Magazine, which contains a minute and circumstantial detail of many important particulars connected with this subject. There appears to be but little doubt that the astronomic refraction was known to the ancients, since it is expressly mentioned by Ptolemy, although not made use of in his calculations. He says, near the end of the 8th book of the Almagest, that in the rising and setting of the heavenly bodies, there are changes which depend upon the atmosphere, and he mentions it more at length in a work on optics, which, unfortunately, has not been handed down to us. Alhazen, an Arabian writer, who is generally supposed to have lived about the year 1100, and to have taken the greater part of his optics from the works of Ptolemy, speaks also decidedly of it, and shews the manner of convincing ourselves of it by experiment. "Take," says he, "an armillary, which turns round its poles, and measure the distance of a star from the pole of the world when it passes near the zenith in the meridian, and when it is rising or setting near the horizon, and you will find the distance from the pole less in the latter case." He then demonstrates that this must arise from refraction, but he does not state its quantity.

In the collection of observations made by Bernard Walter, and published by Willebrode Snell in 1618, it is stated, that the observations were so exact, that they pointed out to Walter the quantities by which the altitudes of the stars and planets were increased on account of the refraction.

Tycho Brahe, however, appears to be the first who asserted, with any degree of accuracy, that the refraction elevates the heavenly bodies rather more than half a degree when on the horizon. (See Progymn. p. 15.) But either his instruments or his observations were not sufficiently correct to determine it with certainty for all degrees from the zenith to the horizon; and, accordingly, where these failed, the rest were supplied by conjecture. He believed that the sun's refraction was 34′ in the horizon, and that it became insensible at 45° of altitude. For the stars, however, he assumed an entirely different quantity, *viz.* 30′ in the horizon; but this, according to him, terminated at only 20° of altitude.

The following is the manner in which it is related (Ency. Method.) that Tycho made this discovery. He had determined, with one or two instruments extremely well made, the latitude of the place by observations of Polaris above and below the pole. He determined it also by the sun's altitude in both solstices, and found it four minutes less in the latter. At first he doubted the goodness of his instruments, and therefore constructed, with the utmost care, as many as ten others, of different sizes and forms, but they all gave nearly the same results. He could, therefore, no longer attribute this difference in the two determinations of the latitude to any defect in the observations, but endeavoured, by an attentive consideration of the subject, to find out the cause of this singular phenomenon. At length he supposed it could only arise from the refraction which elevated the sun at the winter solstice, having then only 11° of elevation above the horizon. This result agreed very well with the principles of optics; but still Tycho Brahe could scarcely persuade himself that the refraction was sufficiently large to produce so great a difference. On this account, he made other instruments of ten feet diameter, whose axes corresponded exactly with the pole of the world, and with these he measured the declination of the stars out of the meridian. He then found, that even in summer the refraction, although insensible at the meridian altitude of the sun, was very considerable near the horizon, and amounted to half a degree in the horizon. See Progymn. p. 79—104. Street's Astr. Carol. p. 119.

Tycho

Tycho Brahe's table of refraction is as follows:

Alt.	Refraction.	Alt.	Refraction.
0°	30′ 0″	°	′ ″
1	21 30	11	5 00
2	15 30	12	4 30
3	12 30	13	4 00
4	11 00	14	3 30
5	10 00	15	3 00
6	9 00	16	2 30
7	8 15	17	2 00
8	6 45	18	1 15
9	6 00	19	0 30
10	5 30	20	0 00

In this ftate the refraction remained for many years. Even Riccioli, in 1665, fuppofed it nothing at about 26° of altitude; but he thought the moon had only 29′ of horizontal refraction in fummer, the fun 30′, and the ftars 30′ 37″. It was not till after the year 1672, that a tolerably near table of refraction made its appearance, when the elder Caffini took the fubject into confideration. (Mem. de l'Acad. tom. v. p. 81.) What led to this was the voyage of Richer to Cayenne in that year, upon the utility of which fome very excellent remarks were made by Caffini, fhewing how far obfervations made in a fituation fo near the equator tended to confirm or difprove certain theories derived from obfervations made in Europe. Several very ufeful deductions were drawn from a comparifon of thofe made both at Paris and Cayenne; among others, the refraction was fettled upon more accurate elements than heretofore, and a new table computed, for the firft time, of its quantity, for all degrees, up to the zenith; an abridgment of which is given below:

Alt.	Refraction.	Alt.	Refraction.
0°	32′ 20″	°	′ ″
1	27 56	30	1 42
2	21 04	40	1 10
3	16 06	45	0 59
4	12 48	50	0 50
5	10 32	60	0 34
10	5 28	70	0 21
15	3 36	80	0 10
20	2 39		

From the relation of his grandfon it appears, however, that Caffini had at one time computed three tables of refraction for all altitudes; one for winter, another for fummer, and a third for fpring and autumn; but feveral doubts having been fuggefted to him refpecting this arrangement, although in appearance conformable to nature, and principally the obfervations of Richer at Cayenne, where the refraction was found little different from that at Paris, he changed his opinion; and judging, that fince the great difference of heat of the torrid zone from that of the temperate zone, which we inhabit, does not caufe fenfible differences in the refraction; therefore the greateft heat or cold of our climate could not change it much; and he then fixed upon one table, which was that ufed by the aftronomers of the Royal Obfervatory of Paris up to the year 1745.

It was always thought, before the time of Caffini, that the refraction did not extend its influence higher than 45° of altitude: and he is generally confidered as the firft who proved that it reached all the way to the zenith. He alfo fuppofed that near the equator the horizontal refraction was lefs than in our climate by about one-third; that this difference decreafed as far up as 60°, after which it was the fame nearly for both climates.

From this difcovery it followed, as a natural confequence, that the refraction muft be greater near the pole than at Paris: and this was fhortly afterwards proved to the Academy by the publication of a work exprefsly on that fubject. (Refractio folis inoccidui, &c. Holmiæ, 4to. 1695.) The king of Sweden, being, in 1694, at Tornea, in Weft Bothnia, near the latitude of 65° 45′, and obferving that the fun did not fet there in the fummer folftice, fent the following year fome mathematicians to make more certain and exact obfervations of this curious phenomenon. They are contained in this book, and Meffrs. Caffini and De la Hire concluded from them, that in the latitude of 65° 45′ the horizontal refraction muft be 58′, or nearly double of that at Paris.

According to an obfervation made by fome Dutchmen who paffed the winter of 1596—7, in Nova Zembla, in latitude 76° north, the fun, which had entirely difappeared the 14th of November, began to rife again the 24th of January, *viz.* fix days fooner than was expected, according to aftronomical calculations. If fo, when the fun has been two or three months under the horizon, as the Dutchmen obferved in 1597, the cold becomes dreadful, and perhaps the refraction increafes prodigioufly. M. le Monnier affures us, that he found by the obfervations printed in 1599, that on the 24th and 27th of January 1597, there were more than $4\frac{1}{2}$ degrees of refraction: that he could neither explain thefe obfervations, reject them as doubtful, nor fuppofe any error, as was done by moft of the other aftronomers, Kepler, Caffini, Scoto, and, laftly, M. le Gentil, in his Voy. dans les Mers des Indes, tom. i. p. 395. tom. ii. p. 832, who maintained that there were errors in the obfervations, and accordingly read a memoir on the fubject. If it were not fo difficult a tafk to winter in thefe high latitudes, we might expect fuch obfervations as would remove all doubt on the fubject; and, perhaps, bring others to light of as great or greater importance.

The refraction of the north being fo confiderable, is very ufeful to the inhabitants, who are deprived of the fun's light during many months; as it makes the fun rife much earlier, and fet much later to them, than it otherwife would.

About the year 1725, Mr. Flamfteed, the Englifh aftronomer royal, publifhed his table computed from his own obfervations: and this was the one commonly ufed in England for many years afterwards.

Sir Ifaac Newton alfo conftructed one from theory, which was firft publifhed by Dr. Halley in the Philofophical Tranfactions, N° 368, for 1721. He made the horizontal refraction 33′ 45″; whereas Mr. Flamfteed's was only 33′ 0″.

But although the refraction might be determined within a few feconds at all altitudes by obfervation; yet, the law of its increafe from the zenith to the horizon was a fubject that occupied the principal mathematicians and aftronomers for more than a century. Newton having difcovered the general principles of attraction, found that the refraction was a confequence of this law of nature; and that it arofe from the attraction of the atmofphere on the particles of light. On this principle the curve which a ray of light defcribes might be determined; fince it is fucceffively attracted

tracted by different layers of the atmofphere, increafing in denfity as they approach the earth, and, confequently, bending the ray more and more from the right line which it defcribed in the vacuum previous to its reaching the atmofphere. There are many authors who have endeavoured to find from theory the curve defcribed by this ray in its courfe, by the affumption of various hypothefes; but perfection, and our attempts to arrive at it, as is well obferved by the elder Caffini in difcourfing on this fubject, are like the progrefs of certain curves and their afymptotes. The principal of thefe writers on the fubject are Bernouilli (Hydrodyn. 1738, p. 221.); Bofcovich (Oper. tom. ii.); Bouguer (Prix de 1729. Memoires, 1739, p. 407; 1749, p. 75.); Caffini (Epift. ad Montanari, 1665. Refrafflioni è Parallaffe, &c. 1671. Mem. for 1714, and his Aftr. vol. i. p. 11. Paris, 1740, in 2 vols. 4to.); Defcartes (Dioptrique, 4to. Paris, 1637); De la Grange (Nouveaux Mémoires de Berlin, vol. iii.); Euler (Mem. de Berlin, 1754, tom. x.); Gregory (Aftronomy, vol. i. p. 358. edit. of 1715, in 8vo.); Hodgfon (Mathematics, vol. i. p. 367. Fluxions, p. 133.); Huygens (Traité de la Lumiere, p. 44. Dioptrica, 4to. 1703); Kramp (Analyfe des Refract. Aftr. et Terres, 4to. Strafburg, 1799); Lambert (Les Proprietés Remarquables de la Route de la Lumiere. A la Haye, 1759. Another edition in German, 1773); La Place (Mécanique Célefte, vol. iv. p. 231.); Mayer (Tables, 1770); Newton (Principia, b. i. fect. 14.); Oriani (Ephem. de Milan. 1788); Thomas Simpfon (Mathematical Differtations, 1743); Brook Taylor (Methodus Incrementorum, 4to. Lond. 1715. Propof. 27. p. 108.); Heinfius (Differtatio de Computo refractionum Aftron. 4to. Leipfig, 1749); Tobias Mayer (De Refractionibus Aftronomicis, 4to. Altorf. 1781); La Hire (Mem. de l'Acad. pour 1702, p. 52.); d'Alembert (Opufcules Mathématiques, tom. viii. p. 297.)

It was conjectured by many of the early writers, that the refraction was fubject to variations depending upon the weather: but it then amounted to little more than a conjecture, on account of the indifferent manner in which aftronomic inftruments were divided. Picard found by meridian altitudes of the fun in 1669, that it was greater in winter than in fummer. He found alfo that it was lefs by day than by night. In the obfervations given at the end of his journey to Uraniburg, to fettle the latitude of that place, and its difference of longitude from Paris, for the purpofe of comparing the obfervations of Tycho Brahe with thofe made at the Royal Obfervatory of Paris, he found the horizontal refraction for the firft limb of the fun that made its appearance above the horizon there 33′ 2″, and for the fecond 32′ 37″. So that in the fmall interval of time that the fun was in rifing, the refraction was diminifhed 25 feconds by the warmth arifing from the fun's prefence.

A quadrant being alfo directed by him from the top of Mount Valerian towards the fummit of the church of Notre Dame at Paris, he found the depreffion 20′; but the fun had fcarcely rifen, when it was increafed to 22′; exhalations being raifed by the fun's prefence, and the medium between Paris and Mount Valerian become more equal; whereas, before the fun rofe, the air of Paris was more denfe than that of Mount Valerian.

The denfity of the atmofphere being the immediate caufe of the refraction, it was very natural to fuppofe that it muft decreafe as this denfity became lefs; whether by caufes which diminifhed its weight, or by the expanfion produced by heat: and, indeed, aftronomers were not long after this, before they difcovered that very fenfible differences were occafioned by thefe circumftances.

But all the honour of introducing corrections on account of the variation of denfity in the atmofphere, as indicated by the barometer and thermometer, is due to Meffrs. Lowthorpe and Haukfbee; the former of whom, in 1698, proved by a very fimple experiment, in the prefence of the Royal Society, that the refractive power of air is directly proportional to its denfity: and the latter, by repeating and extending the fame courfe of experiments in the year 1708, with the machinery pointed out by the former, found that the variations of refraction, depending on the barometer, are proportional to the alteration of height of the mercury in the tube: and by a feries of thefe experiments, he furnifhed us with a table of the corrections which it is neceffary to make on account of the changes of heat indicated by the thermometer. Thefe experiments, although not quite conclufive on the fubject, were yet made with as much accuracy and care as the nature of the machinery, and the ftate of experimental philofophy of that time, would admit. An example is alfo given, towards the end of his paper, on the mode of applying them to correct the refraction. By thefe, Haukfbee found that a volume of air expreffed by unity, when the thermometer was at 180° above zero, became, at 50° below, one-eighth more denfe: or, which is the fame thing, that the air loft one-eighth of its denfity, for an elevation of 180° of Fahrenheit's thermometer; which is exactly the difference of heat between melting ice and boiling water. But although this one-eighth, as will be fhewn hereafter, was too fmall; yet it laid the foundation for other experiments, fince made by feveral philofophers, by which the quantity of expanfion has been determined more accurately.

We have already fhewn that the refraction near the pole is greater than in our climate; the degree of cold being more intenfe. It was alfo found to be lefs in the torrid zone, where the heat is greater than in Europe. Bouguer made a variety of obfervations at Peru, the refult of which he has given us. In 1740, he came down into an ifland fituated in the river of Emeralds, called ifle of Inca, where he determined the refraction from 1° to 7° of altitude; and the table which he afterwards computed fhews the refraction to be about one-feventh lefs than in Europe. The horizontal refraction he found to be 27′: but at 6° of altitude it is 7′ 4″; and at 45°, it is 44″. Bouguer then gives a table for Quito, which is more elevated above the level of the fea. M. le Gentil found it greater at Pondicherry in India, although in the torrid zone.

The refraction diminifhes when we are elevated above the level of the fea. Bouguer obferved the quantity of it at Chimboraço, 2388 toifes above the level of the fea, and found it in the horizon only $19\frac{3}{4}$′. At the crofs of Pitchinca, 2044 toifes above the fea, he found it 20′ 48″; at Quito, 1479 toifes above the fea, 22′ 50″: but at the level of the fea 27′. Thefe obfervations, when joined with the theory, produced the following rule; *viz.* if we take the excefs of 5158 toifes above the elevation of the place, with regard to the level of the fea, the refraction will be as the fquare root of this excefs. Thus the fquare root of 5158 toifes is 27′, for the horizontal refraction, at the level of the fea, in the torrid zone: and the fquare root of the excefs of 5158 above the elevation of the place will be its horizontal refraction. The quantity 5158 is the height above which the refractive matter no longer produces any fenfible effect, at leaft in the torrid zone.

But although by this time confiderable attention had been paid to the fubject, yet great differences were to be found in the tables then moft in ufe. Thus at the altitude of 30°, according to Flamfteed, the refraction was 1′ 23″; Newton, 1′ 30″; Caffini, 1′ 42″; and de la Hire, 1′ 55″; leaving an uncertainty of more than half a minute: and it muft have been very mortifying to an obferver, after having taken the utmoft utmost pains to avoid errors of two or three feconds, to find his reduced obfervations liable to fo great an error, according to the choice of his table of refraction.

It is indeed rather extraordinary, that in a memoir publifhed by Caffini de Thury, among thofe of the Academy for 1745, he attempted to reconcile a number of obfervations with each other, by confidering the ftate of the thermometer only, without at all noticing that of the barometer; although at that time Haukfbee's experiments had been publifhed about 37 years.

He concludes his paper, as is very natural to fuppofe, without being able to make the obfervations agree: nor does it clearly appear that the French noticed the abovementioned experiments made by Haukfbee till about the year 1749. It is alfo worthy of remark, that although the neceffity of introducing corrections on account of the alterations of the barometer and thermometer were likewife fhewn to be abfolutely neceffary by Dr. Halley (Phil. Tranf. N° 364), and the circumftance mentioned, and in fome degree admitted by Le Monnier (Hift. Celeft.), yet it does not appear that he followed the advice of his illuftrious contemporary, but merely endeavoured, as Caffini did, to reconcile his obfervations with the ftate of the thermometer at the time of making thefe obfervations, without taking the barometer into account.

It would be endlefs to notice the different opinions refpecting both the terreftrial and the aftronomic refraction which are to be met with in the writings of various authors on the fubject: and it would be equally ufelefs to notice all the tables of its quantity given by them, fome of which differ very much from others. It will be fufficient to mention thofe only who made fome confiderable advances towards obtaining it with greater accuracy.

The next of thefe in order was La Caille (Mem. de l'Ac. de Sc. 1755, p. 547.), who in determining it certainly beftowed very great pains, by making and reducing an immenfe number of obfervations, and afterwards comparing them with others made at Greenwich by Dr. Bradley, at Gottingen by Mayer, at Bologna by Zanotti, and by La Lande, who was then at Berlin. From thefe it appeared that the refraction at 45° of altitude was $1' \, 6\frac{1}{2}''$; but this, as will hereafter be feen, was too great by fome feconds. In his paper on the fubject, which is divided into four parts, he proves, firft, that the mean refractions are very nearly the fame for the fame apparent altitudes throughout the whole extent of the temperate zone; fince thofe which were obferved at Paris did not exceed thofe obferved at the Cape of Good Hope but by $\frac{1}{40}$ at moft. In the fecond he determines the abfolute quantity of the mean refraction for the apparent height of the pole at Paris, and gives the refult of his obfervations with regard to the latitude of Paris and of the Cape of Good Hope. In the third he gives his table of mean refraction, and another of corrections depending upon the ftate of the barometer and thermometer; concluding with fome reflections on its conftruction and ufe. In the fourth he compares his new table with the moft celebrated of thofe that had before that time been in ufe among aftronomers; and he then fhews how it agrees with the obfervations of Bradley, Zanotti, and Mayer.

But by La Caille's memoir it appears, that previous to this time M. Mayer had formed and communicated to him a table of aftronomic refractions which he computed by means of an algebraic formula, the co-efficients of which he deduced from his own obfervations, and took into account the variations relative to thofe of the barometer and thermometer. He found the alteration of refraction for a depreffion of 15 lines in the barometer, the fame as for a rife of 10° in the thermometer, and the variation for each degree of the latter, according to his table, $\frac{1}{71}$ of the whole mean refraction, which he adapted for 28 inches of the barometer, and 0° of the thermometer. This proportion takes place down to 80° of zenith diftance. Mayer confidered alfo that the mean refraction is the fame for all parts of the earth; and that the only variation which takes place depends on the changes of the weight and temperature of the atmofphere.

La Caille, in comparing Mayer's table with obfervations, found that his correction for the thermometer was a little over-rated; and accordingly, for his new table, altered it to $\frac{1}{77}$ for each degree. And here it may be obferved that La Caille did not correct his altitudes above 36 at Paris, and 30° at the Cape; firft, becaufe he only noted the barometer and thermometer in the night, when he obferved ftars below 30° of altitude. Secondly, becaufe, that at 36° of altitude, where the mean refraction is about $1\frac{1}{2}$ minute, the variation which belongs to 10° of the thermometer only amounts to $3\frac{1}{2}$ feconds; a quantity about equal to the limits of the errors of obfervations made with an inftrument of fix feet.

The formula given by Euler (Mem. de l'Ac. de Berlin, 1754, p. 131.), appeared alfo about this time. It took into account the variation of the refraction depending upon the thermometer and barometer, but was certainly too complicated to be generally adopted. He fhews, however, that in very different hypothefes the refraction will be fufficiently exact, if taken in the inverfe ratio of the degrees of heat, when the ftar or planet is not too near the horizon, but the precife quantity of this ratio was unknown to him.

In this ftate the refraction ftood when Dr. Bradley took the fubject into confideration, and began to find its quantity from his own obfervations. The rule which he adopted, although a very elegant one, he neither lived to complete nor to prefent to the world; but it was publifhed after his death by Dr. Mafkelyne, (Pref. to 1ft vol. of Obf. 1765. Phil. Tranf. 1764 and 1787, p. 157. Req. Tables, &c.), and has commonly been ufed in England up to the prefent time. He found the mean refraction at 45° of altitude 57″, and, that at all other altitudes, it was equal to 57″ multiplied by the tangent of the zenith diftance, diminifhed by three times the refraction. Then fuppofing the mean ftate of the atmofphere to be at 29.6 inches of the barometer, and 50° of Fahrenheit's thermometer, he made the true or corrected refraction equal to $57'' \times t, (\text{Z. D.} - 3r) \times \frac{\text{barom.}}{29.6} \times \frac{400}{350 + \text{ther.}}$, where it is to be underftood that the mafs of air is fuppofed to increafe in bulk $\frac{1}{400}$ for each degree of Fahrenheit's fcale.

A variety of experiments has been made at various times to afcertain the increafe in bulk of a quantity of air reprefented by unity for a certain number of degrees of rife of the thermometer. The following is a lift of fome of them:

	for 1°
M. Bonne	1.00 25777
Bradley	1.00 25000
Dalton	1.00 20701
De Luc	1.00 20888
Fahrenheit	1.00 25777
Gay Luffac	1.00 20868
Groombridge	1.00 21000
Haukfbee	1.00 06933
La Caille	1.00 22222
Mayer	1.00 20444
Shuckburg	1.00 22222
Mean of all except Haukfbee's	1.00 22490

The

The refraction deduced from Bradley's very neat and fimple formula was, in a few years, adopted by nearly all the aftronomers of eminence throughout Europe. The extreme facility with which it might be computed, and the corrections applied, whether from the formula itfelf, or from tables ready calculated for that purpofe, was a powerful recommendation in its favour; but its near agreement with obfervation foon eftablifhed it.

We muft now, without entering farther into detail of minor improvements, proceed at once to the chapter given by La Place on this fubject, in his "Mecanique Celefte," vol. iv. p. 231, where he has drawn, from an inveftigation which we cannot undertake to exhibit in this place, the following general formula, for expreffing the refraction for all angles of elevation above 12 decimal, or 10.8 fexagefimal degrees, *viz.*

$$r = \frac{a p \,.\, \text{tan.}\, z}{0.76\,(1 + t \,.\, 0.00375)} - \frac{a p}{0.76} \,.\, 0.00125254\, \frac{\text{tan.}\, z}{\text{cof.}^2\, z}$$
$$+ \frac{\frac{1}{2} a^2\, \text{fin.}\, 1''\, p^2}{[0.76(1 + t \,.\, 0.00375)]^2} \times \frac{(1 + 2\, \text{cof.}^2\, z)\, \text{tan.}\, z}{\text{cof.}^2\, z};$$

where all the quantities are known except r and a; which latter reprefents a conftant co-efficient; *viz.* z is the obferved zenith diftance under the barometric preffure p, in metres, and t the temperature of the centigrade thermometer, r being the refraction: all, therefore, that is required for determining r, is the value of the unknown coefficient a; which is to be drawn from obfervations on the circumpolar ftars, in the following manner.

Let Z be the diftance of one of thefe ftars from the zenith, in its fuperior meridian paffage; Z′, this diftance at the inferior meridian paffage, obferved from the fame point of the terreftrial furface; r and r', the correfponding refractions. Now all the other quantities, except a, being known, we may, for the fake of fimplicity, put the above formula for both paffages under this form,

$$r = \mathrm{A}\,a + \mathrm{B}\,a^2,\quad r' = \mathrm{A}'a + \mathrm{B}'a^2;$$

where A, B, A′, B′, are all known quantities. Writing alfo Z, Z′, for the obferved zenith diftances, the true zenith diftance, D, corrected for refraction, will be

$$\mathrm{Z} + \mathrm{A}\,a + \mathrm{B}\,a^2, \text{ and } \mathrm{Z}' + \mathrm{A}'a + \mathrm{B}'a^2,$$

which are, therefore, now equal to each other; confequently, by addition, we have

$$\mathrm{Z} + \mathrm{Z}' + (\mathrm{A} + \mathrm{A}')\,a + (\mathrm{B} + \mathrm{B}')\,a^2 = 2\,\mathrm{D};$$

in which all the quantities are known, except a and D. But by repeating fimilar obfervations on fome other ftar, and denoting by Z″, Z‴, A″, A‴, B″, and B‴, the fimilar quantities before reprefented by Z, Z′, A, A′, &c. alfo a and D remaining the fame for all ftars obferved in the fame place, we fhall have thefe two equations:

$$\mathrm{Z} + \mathrm{Z}' + (\mathrm{A} + \mathrm{A}')\,a + (\mathrm{B} + \mathrm{B}')\,a^2 = 2\,\mathrm{D},$$
$$\mathrm{Z}'' + \mathrm{Z}''' + (\mathrm{A}'' + \mathrm{A}''')\,a + (\mathrm{B}'' + \mathrm{B}''')\,a^2 = 2\,\mathrm{D};$$

from which it is obvious, the conftant co-efficient a may be obtained by the ufual methods of elimination.

In the above operation, however, we have fuppofed the polar diftances of the fame ftar to be the fame for its fuperior and inferior paffage; whereas we know that, in confequence of the effect of preceffion, nutation, and aberration, this diftance is conftantly varying; and we ought, therefore, to introduce thefe variations into the above equation. But our object being merely to give a general view of the principles made ufe of for the determination of the co-efficient a, we have not thought it neceffary to enter fo ftrictly into the minutia of the computation. It appears from the above, that the conftant co-efficient a may be determined by means of four obfervations on two different circumpolar ftars; and confequently, that every fuch fet of obfervations ought to produce the fame refult, or the fame value of a. Confidering, however, the extreme accuracy required in fuch cafes, both in the inftruments and the application of them, fome little difagreement is to be expected; and indeed one is furprifed to fee it fo fmall, as it has been found to be in various obfervations undertaken for this purpofe, and the mean of which we have every reafon to confider as perfectly correct; and which is ftated by M. Biot, who has interefted himfelf very much on this fubject, at 187″.24 for the decimal divifion, or 60″.666 for the fexagefimal.

But now, in order to fimplify our firft formula, by taking $p = 0.76$ metres, and $t = 0$, this may be put under the form,

$$r = a\, \text{tan.}\, \mathrm{Z}\, \left(1 - \frac{0.00125254}{\text{cof.}^2\, z}\right) + \tfrac{1}{2} a^2\, \text{fin.}\, 1''\, \frac{1 + 2\, \text{cof.}^2\, z}{\text{cof.}^2\, z}$$
$$\text{tan.}\, \mathrm{Z};$$

in which, fubftituting for cof.$^2 z$, its value $\frac{1}{1 + \text{tan.}^2 z}$, and the proper numerical value of a, as above found, as alfo of fin. 1″, the whole is reduced to the following form, *viz.*

$$r = 0.99918761 \,.\, a\, \text{tan.}\, \mathrm{Z} - 0.001105823 \,.\, a\, \text{tan.}^3\, \mathrm{Z};$$

which latter form M. Biot has fhewn to be equivalent to

$$r = 187''.24 \,.\, \text{tan.}\, (\mathrm{Z} - 3.25\, r) \text{ for the decimal divifion;}$$
$$r = 60''.666 \,.\, \text{tan.}\, (\mathrm{Z} - 3.25\, r) \text{ for the fexagefimal divifion.}$$

But the reduction of it to this form would occupy more fpace than can be allowed for this article. This laft form is as fimple as can be defired, from which the following rule in words may be deduced, *viz.* *The refraction under the fame barometric preffure, and the fame degree of temperature, is proportional to the tangent of the apparent zenith diftance of the ftar, diminifhed by* $3\frac{1}{4}$ *times the refraction.*

It muft be remarked, however, that the formula $r = \mathrm{A}$ tan. $(\mathrm{Z} - 3.25\, r)$, though it exhibits the law of refraction in as fimple a form as can be defired, is not well adapted for calculation, in confequence of r entering on both fides of the equation; and aftronomers have, therefore, given different methods of rendering the above formula more commodious. In order to which, it is firft put under the form,

$$\text{tan.}\, n r = \text{tan.}^2\, n\, \mathrm{R}\, \text{tan.}\, (\mathrm{Z} - n r);$$

R reprefenting the refraction, anfwering to Z = 90°. Let us now add fucceffively to both fides of this equation, the quantities + tan. $n r$ tan.$^2 n$ R − tan. $n r$ tan.$^2 n$ R, and we fhall have,

$$\text{tan.}\, nr\,(1 + \text{tan.}^2 n\,\mathrm{R}) = \text{tan.}^2 n\,\mathrm{R}\,[\text{tan.}\,(\mathrm{Z} - nr) + \text{tan.}\, nr],$$
$$\text{tan.}\, nr\,(1 - \text{tan.}^2 n\,\mathrm{R}) = \text{tan.}^2 n\,\mathrm{R}\,[\text{tan.}\,(\mathrm{Z} - nr) - \text{tan.}\, nr].$$

Now, dividing thefe equations, member by member, $n r$ will be eliminated, and we obtain

$$\frac{1 + \text{tan.}^2 n\,\mathrm{R}}{1 - \text{tan.}^2 n\,\mathrm{R}} = \frac{\text{tan.}\,(\mathrm{Z} - n r) + \text{tan.}\, n r}{\text{tan.}\,(\mathrm{Z} - n r) - \text{tan.}\, n r},$$

$$\text{or } \frac{1}{\text{cof.}\, 2\, n\, \mathrm{R}} = \frac{\text{fin.}\, \mathrm{Z}}{\text{fin.}\, (\mathrm{Z} - 2\, n\, \mathrm{R})};$$

whence we draw

$$\text{fin.}\, (\mathrm{Z} - 2\, n r) = \text{cof.}\, 2\, n\, \mathrm{R} \,.\, \text{fin.}\, \mathrm{Z}.$$

Now

Now Z and n R being known, we may compute the fecond fide of this equation; whence the arc Z — $2nr$ is known, and confequently $2nr$; which, divided by $2n$, will give r, as required. But it may be found ftill more fimply by the formula,

$$\tan.\ ur = \tan.\ n\,R\ \tan.\ \tfrac{1}{2}\,n;$$

tan. n being found by means of the auxiliary equation,

$$\tan.\ u = \sin.^2\ n\,R\ .\ \tan.\ Z.$$

On the principle above explained, the following table of refractions has been computed, agreeing with the temperature of + 14° on the centigrade thermometer, and under a preffure of 0.76 metres of the barometer; which is the fame as 57°.2 Fahrenheit, and 29.922 Englifh inches. And for any other temperature and preffure, the correfponding corrections muft be made as indicated in Tables II. and III.; which tables are computed by means of the general formula given in the preceding part of this article.

We had intended to give here a fhort abftract of a very interefting paper on this fubject, publifhed by Mr. Groombridge, in the Philofophical Tranfactions for 1810; but having already exceeded our ufual limits, we can only refer the reader to the volume itfelf, where he will find feveral neat and ufeful formulæ.

Having thus given a fketch of the method of determining the quantity of aftronomical refraction for all angles of elevation, and under various degrees of temperature and barometric preffure, let us add a few words on the fubject of terreftrial or horizontal refraction; for the determination of which, the following method has been fuccefsfully practifed in the Englifh Trigonometrical Survey.

Let A, A′, (*Plate* XIX. *Aftronomy*, *fig.* 11.) be two elevated places on the furface of the earth; B D, the intercepted arc of the earth's furface; C, the centre of the earth; A H′, A′ H, the horizontal lines at A, A′, produced to meet the oppofite vertical lines C H′, C H. Let a, a', reprefent the apparent places of the objects A, A′; then is a' A A′ the refraction obferved at A, and a A′ A the refraction obferved at A′; and half the fum of thefe angles will be the horizontal refraction, if we affume it equal at each ftation.

Now an inftrument being placed at each of thefe ftations A, A′, the reciprocal obfervations are made at the fame inftant of time, which is determined by means of fignals or watches previoufly regulated for that purpofe; that is, the obferver at A takes the apparent depreffion of A′, at the fame moment that the other obferver takes the apparent depreffion of A. Then, in the quadrilateral A C A′ I, the two angles A, A′, are right angles, and confequently the angles I and C are together equal to two right angles; but the three angles of the triangle I A A′, are together equal to two right angles; and confequently the angles A and A′ are together equal to the angle C, which is meafured by the arc B D. If, therefore, the fum of the two depreffions H A′ a, H′ A a, be taken from the fum of the angles H A′ A, and H′ A A′, or, which is equivalent, from the angle C, (which is known, becaufe its meafure B D is known,) the remainder is the fum of the two refractions. Hence this rule, "take the fum of the two depreffions from the meafure of the intercepted terreftrial arc, half the remainder is the refraction." If, by reafon of the minutenefs of the contained arc B D, one of the objects, inftead of being depreffed below the tangent A H′, appears elevated, as fuppofe A to a'', then the fum of the angles a'' A A′, and a A′ A, will be greater than the fum I A A′ + I A′ A, or than C, by the angle of elevation a'' A A′; but if from the former fum there be taken the depreffion H A′ A, there will remain the fum of the two refractions, fo that in this cafe the rule becomes as follows: "Take the depreffion from the fum of the contained arc and elevation, and half the remainder is the refraction."

The quantity of this terreftrial refraction is eftimated by Dr. Mafkelyne at one-tenth of the diftance of the object obferved, expreffed in degrees of a great circle. Whence, if the diftance be 10,000 fathoms, its 10th part, 1000 fathoms, is the 60th part of a degree, or one minute, which, therefore, is the refraction in altitude of the object at that diftance. But Le Gendre is induced, by feveral experiments, to allow only one-fourteenth part of the diftance for the refraction in the altitude, fo that on the diftance of 10,000 fathoms, the 14th part of which is 714 fathoms, he allows only 44″ of terreftrial refraction, fo many being contained in 714 fathoms. (See his Memoir on the Trigonometrical Operations.) Again, Delambre makes the quantity of terreftrial refraction to be one-eleventh part of the arc of diftance. And the Englifh meafurers, from many very exact obfervations, determine the quantity of the medium refraction to be a twelfth part of the faid diftance. The mean of all thefe is about .085 of the intercepted arc, which is probably not very far from the truth: this quantity, however, it muft be obferved, is found to vary very confiderably with the different ftates of the weather and atmofphere, from one-feventh to one-eighteenth of the contained arc.

TABLE

TABLE I. Of Refraction.

Barometer 29.922 Inches = 0.76 Metre; Thermometer Centigrade, 14°; Fahrenheit's, 57°.2; Reaumur's, 11°.2.

To observe the Refraction of a Star, &c. 1. Observe the meridian altitude of a star near the zenith; whence the latitude of the place being known, the true declination of the star is easily had, the star being now void of any sensible refraction. 2. Observe the altitude of the same star in any other degree, and note the time by a pendulum. 3. For the given time of observation, from the declination of the star compute its true altitude.

This being thus found less than the altitude observed, subtract the one from the other; and the remainder is the refraction for that moment, in that degree.

Refraction *of Altitude*, is an arc of a vertical circle, by which the altitude of a star is increased by the refraction.

Refraction *of Declination*, is an arc of a circle of declination, by which the declination of a star is increased or diminished by the refraction.

Refraction *of Ascension and Descension*, is an arc of the equator, by which the ascension and descension of a star, whether right or oblique, is increased or diminished by means of the refraction.

Refraction *of Longitude*, is an arc of the ecliptic, by which the longitude of a star is increased or diminished by means of the refraction.

Refraction *of Latitude*, is an arc of a circle of latitude, by which the latitude of a star is increased or diminished by means of refraction.

Refraction, in *Commerce*, is a term sometimes used by merchants, where there has been an oversight in an account, to the prejudice of a person; who thereupon demands restitution of so much, added or omitted by mistake.

You must make me a refraction of five pounds forgot in your account. I will deduct or make you a refraction of 30*s*. charged inadvertently in my bill.

REFRACTORY, in *Chemistry*. See an explication of the term under Apyrous.

REFRAIN, Fr., in *Music*, the termination of every verse or stanza of a song, by the same words and the same melody. (See Burden.) The word, according to Menage (Dict. Etym.) is derived from the Spanish *refran*.

REFRAN, Span., a proverb; the burden of a song in that language, being usually sententious, and including some moral precept.

REFRANGIBLE, whatever is capable of being refracted. See Refrangibility.

REFRANGIBILITY *of Light*, the disposition of the rays to be refracted.

A greater or less refrangibility is a disposition to be more or less refracted, in passing at equal angles of incidence, into the same medium.

That the rays of light are differently refrangible, is the foundation of sir Isaac Newton's whole theory of light and colours. The truth of the principle, which was investigated and established by our great philosopher in the year 1616, will appear from the following experiments.

1. Let E G (*Plate* XIX. *Optics*, *fig.* 1.) represent the window-shutter of a dark room, and F a hole in it, through which the light is transmitted to the prism A B C, which refracts it towards P T, where it appears in an oblong form; its length being about five times greater than its breadth, and exhibiting the various colours of the rainbow. In *fig.* 2. *a g b* represents a second prism, which refracts the light back again to Q, where the image is round; whereas, without the interposition of this second prism, the light would have proceeded to P T, and, consequently, have been oblong, as before. In this experiment sir Isaac Newton took care that the plane *a g* was placed exactly parallel to B C, and also *b g* to A C, that the rays might be equally refracted, though in contrary ways, by both prisms. He also observed, that both prisms must be placed very near to one another; for if their distance be so great, that colours begin to appear in the light, before its incidence on the second prism, those colours will not be destroyed by the refraction of that prism.

2. Having placed one of two boards behind the prism at the window, so that the light might pass through a small hole made in it for the purpose, and fall on the other board at the distance of about twelve feet, a hole being made in it to admit the passage of the incident light, he then placed another prism behind the second board, so that the light which was transmitted through both the boards, might pass through that also, and be again refracted before it arrived at the wall. This being done, he took the first prism in his hand, and turned it about its axis so much, as to make the several parts of the image, cast on the second board, successively to pass through the hole in it, that he might observe to what places on the wall the second prism would refract them; and he saw, by the change of those places, that the light tending to that end of the image, towards which the refraction of the first prism was made, did, in the second prism, suffer a refraction considerably greater than the light which tended to the other end. The true cause, therefore, of the length of that image was discovered to be no other, than that light is not similar or homogeneal, but that it consists of rays, some of which are more refrangible than others; so that without any difference in their incidence on the same medium, some of them shall be more refracted than others; and therefore, that according to their particular degrees of refrangibility, they will be transmitted through the prism to different parts of the opposite wall.

To make this capital experiment, which sir Isaac Newton himself justly calls the *experimentum crucis*, let S F (*fig.* 3.) represent a ray of the sun, which, after passing through a hole in the window-shutter F, is received by the prism in A B C, close behind which is placed a board D E, with a hole in it at G, to admit any of the rays after they have been separated by the prism; then *d e* will represent the other board, placed at a considerable distance from the former, with a hole in it, *g*, to receive any part of the light transmitted through the other board. Behind this second board is placed another prism, *a b c*, through which different rays of light, falling upon it in the very same place, and with precisely the same angle of incidence, will be refracted higher or lower, on the opposite wall M N. This experiment was conducted with the utmost circumspection and accuracy; and it is observed, that neither the different magnitude of the hole in the window-shutter, nor the different thicknesses of the prism, at the place where the rays passed through it, nor the different inclinations of the prism to the horizon, nor the different matter of the prisms, made any sensible change in the length of the image.

3. In order farther to establish this famous hypothesis of the different refrangibility of the rays of light, he held a prism in a beam of the sun, which was transmitted into the room through a hole in the window-shutter, so that its axis might be perpendicular to that beam; and having turned the prism about its axis to make the image ascend and descend, and when it seemed to be stationary between these contrary motions, he fixed the prism so that the refractions of both sides might be equal to each other. In this situation he looked at the hole through the prism, and observed the length of its refracted image to be many times greater than its breadth: the most refracted part of it was violet, the least refracted red, the middle parts blue, green, and yellow, in order. The same thing happened when he removed the prism out

out of the ſun's light, and looked through it upon the hole ſhining by the light of the clouds beyond it.

4. Conſidering that if the image of the ſun ſhould be drawn into an oblong form, either by a dilatation of every ray, or by any other caſual inequality of the refractions, the ſame oblong image would, by a ſecond refraction, made ſideways, be drawn out as much in breadth, he placed a ſecond priſm immediately after the firſt, in an oblique poſition with reſpect to it, that it might again refract the light of the beam of the ſun's light, which came to it through the firſt priſm; ſo that in the firſt priſm, the beam would be refracted upwards, and in the ſecond ſideways. But he found that the breadth of the image was not increaſed by the refraction of the ſecond priſm, but only its upper part, which in the firſt priſm ſuffered the greateſt refraction, and appeared violet and blue, did again, in the ſecond priſm, ſuffer a greater refraction, than the lower part of it, which was red and yellow, and this without any dilatation of the breadth of the image. Thus let S (*fig.* 4.) repreſent the ſun, F the hole in the window, A B C the firſt priſm, and D H the ſecond. If Y repreſent the round image of the ſun, made by a direct beam of light, when the priſms are taken away, P T will be the oblong image of the ſun, made by the ſame beam paſſing through the firſt priſm only, and *p t* will be the image made by the croſs refractions of both priſms together. Sometimes he placed a third priſm after the ſecond, and ſometimes a fourth after the third; by all which the image might be often refracted ſideways, but the rays which were more refracted than the reſt in the firſt priſm, were alſo more refracted in all the others, and that without any dilatation of the image ſideways; and, therefore, thoſe rays, on account of their conſtancy of a greater refraction, he called the more refrangible ones. He obſerves, in order to render the meaning of this experiment more evident, that all the rays, which are equally refrangible, fall upon a circle anſwering to the ſun's diſc. Let, therefore, A G (*fig.* 5.) repreſent the circle which all the moſt refrangible rays, tranſmitted from the whole diſc of the ſun, would illuminate, and paint upon the oppoſite wall, if they were alone. Let E L be the circle which all the leaſt refrangible rays would, in like manner, illuminate, and paint, if they were alone, and let B H, C J, and D K, be the circles which ſo many intermediate kinds of rays would ſucceſſively paint upon the wall, if they were ſingly propagated from the ſun, the reſt being always intercepted, and conceive that there are other intermediate circles without number, which other innumerable intermediate kinds of rays would ſucceſſively paint upon the wall, if the ſun ſhould ſucceſſively emit every kind by itſelf. Now ſince the ſun emits rays of all theſe kinds at once, they muſt altogether illuminate and paint innumerable equal circles, of all which, being ranged according to their different degrees of refrangibility, the oblong image P T before deſcribed is compoſed.

Now if the ſun's circular image, Y, which is made by an unrefracted beam of light, was by any dilatation of the ſingle rays, or by any other irregularity in the refraction of the firſt priſm, converted into the oblong image P T, then ought every circle in the image to be in like manner drawn out into a ſimilar oblong figure, contrary to the reſult of this experiment.

He conſidered farther, that by the breadth of the hole through which the light enters into the dark chamber, there is a penumbra made in the circumference of the image Y, which is alſo viſible at the ſides of the oblong images P T and *p t*. He, therefore, placed at that hole a lens, or object-glaſs of a teleſcope, which might caſt the image of the ſun diſtinctly on Y, without any penumbra at all; and he found that the penumbra of the rectilinear ſides of the oblong images P T and *p t* was alſo thereby taken away, ſo that they were as diſtinctly defined as the circumference of the firſt image Y.

There are ſome other circumſtances attending this experiment, by which the concluſion drawn from it is made ſtill more plain and convincing.

Let the ſecond priſm, D H, (*fig.* 6.) be placed not immediately after the firſt, but at ſome diſtance from it, ſo that the light from the firſt priſm may fall upon it in the form of an oblong ſpectrum *q r*, parallel to this ſecond priſm, and may be refracted ſideways, to form the oblong image, *p t*, upon the wall, and it will be found that this image, *p t*, is inclined to the image P T, which the firſt priſm would have formed without the ſecond; the blue ends, P and *p*, being farther diſtant from one another than the red ones, T and *t*; and, conſequently, the rays which go to the blue end, *q*, of the image *q r*, and which, therefore, ſuffer the greateſt refraction in the firſt priſm, are again, in the ſecond priſm, more refracted than the reſt.

At two holes made near one another in his window-ſhutter, he placed two priſms, one at each, which might caſt upon the oppoſite wall two oblong coloured images of the ſun; and at a little diſtance from the wall he placed a long ſlender paper, with ſtraight and parallel edges; and he placed the priſms and papers, ſo that the red colour of one image, at T, (*fig.* 7.) might fall directly upon one half of the paper, and the violet colour, M, of the other image, upon the other half of the ſame paper. Then with a black cloth he covered the wall behind the paper, that no light might be reflected from it to diſturb the experiment; and viewing the paper through a third priſm, held parallel to it, he ſaw that half of it which was illuminated by the violet light to be divided from the other half, by a greater refraction, eſpecially when he retired to a conſiderable diſtance from the paper.

He farther cauſed the two images, P T and M N (*fig.* 8.) to coincide, in an inverted order of their colours, the red end of each falling on the violet end of the other; and then viewing them through a priſm D H, held parallel to their length, they no longer appeared coincident, as when they were viewed with the naked eye, but in the form of two diſtinct images, *p t* and *m n*, croſſing one another in the middle; which ſhews that the red of the one image, and the violet of the other, which were coincident at P N and M T, being parted from one another by a greater refraction of the violet to *p m*, than that of the red to *n* and *t*, differ in degree of refrangibility.

Having placed a priſm, whoſe two angles at its baſe were equal to one another, and half right ones, and the third a right one, in a beam of the ſun's light, admitted into the room as before, he turned it ſlowly about its axis, till all the light which went through one of its angles, and was refracted by it, began to be reflected by its baſe, (at which, till then, it went out of the glaſs,) and then he obſerved that thoſe rays which had ſuffered the greateſt refraction were ſooner reflected than the reſt. He imagined, therefore, that thoſe rays of the reflected light, which were moſt refrangible, did firſt of all, by a total reflection, become more copious in that light than the reſt; and that afterwards the reſt, alſo, by a total reflection, became as copious as theſe. To try this, he made the reflected light paſs through another priſm, and, being refracted by it, to fall afterwards upon a ſheet of white paper, at ſome diſtance behind it, and there to paint the uſual colours of the priſm. Then cauſing the firſt priſm to be turned about its axis, he obſerved, that when thoſe rays which, in this priſm, had ſuffered the greateſt

greateſt refraction, and were of a blue and violet colour, began to be wholly reflected, the blue and violet light on the paper, which received the rays from the ſecond priſm, was ſenſibly increaſed, above that of the red and yellow, which was leaſt refracted; and afterwards, when the reſt of the light, which was green, yellow, and red, began to be wholly reflected in the firſt priſm, the light of thoſe colours on the paper received as great an increaſe as the violet and blue had done before. From this it is manifeſt, that the beam reflected by the baſe of the priſm, being augmented firſt by the more refrangible rays, and afterwards by the leſs refrangible ones, is compounded of rays differently refrangible. This experiment is illuſtrated by *fig.* 9, in which A B C repreſents the firſt priſm, on the baſe of which the light falls, at M. When this priſm is turned about its axis, according to the order of the letters A B C, the more refrangible rays, M H, emerge more and more obliquely; and at length, after their moſt oblique emergence, are reflected towards N, and going on to *p*, increaſe the number of rays N *p*. By continuing the motion of the firſt priſm, the leſs refrangible rays, M G, are reflected to N, and increaſe the number of rays N *t*.

Since it appears from ſir Iſaac Newton's experiments, that different rays of light have different degrees of refrangibility, it neceſſarily follows that the rules laid down by preceding philoſophers, concerning the refractive power of water, glaſs, &c. muſt be limited to the middle kind of rays, as it may be ſuppoſed that Kepler, Snellius, and others would attend to them principally. Sir Iſaac, however, proves that the ſine of the incidence of every kind of light, conſidered apart, is to its ſine of refraction in a given ratio. This he deduces both by experiment, and alſo geometrically, from the ſuppoſition that bodies refract the light by acting upon its rays in lines perpendicular to their ſurfaces.

Upon the whole it appears, that the blue rays are more refracted than the red ones, and that there is, likewiſe, unequal refraction in the intermediate rays; and upon the whole it appears, that the ſun's rays have not all the ſame refrangibility, and, conſequently, are not of the ſame nature. It is alſo obſerved, that thoſe rays which are moſt refrangible are alſo moſt reflexible. See the proof of this under REFLEXIBILITY. Newton's Optics, p. 22, &c. ed. 3.

The difference between refrangibility and reflexibility was firſt diſcovered by ſir Iſaac Newton, in 1671-2, and communicated in a letter to the Royal Society, dated February 6, 1671-2, and publiſhed in the Philoſophical Tranſactions, N° 80, p. 3075, and from that time vindicated by him from the objections of ſeveral authors; particularly F. Pardies, M. Mariotte, Fr. Linus, or Lin, and other gentlemen at the Engliſh college at Liege; and at length it was more fully laid down, illuſtrated, and confirmed, by a great variety of experiments, in his excellent treatiſe of Optics.

But farther, as not only thoſe colours of light produced by refraction in a priſm, but alſo thoſe reflected from opaque bodies, have their different degrees of refrangibility and reflexibility; and as a white light ariſes from a mixture of the ſeveral coloured rays, the ſame great author concluded all homogeneous light to have its proper colour, correſponding to its degree of refrangibility, and not capable of being changed by any reflections, or any refractions; that the ſun's light is compoſed of all the primary colours; and that all compound colours ariſe from a mixture of the primary ones, &c.

The different degrees of refrangibility he conjectures to ariſe from the different magnitude of the particles of which the different rays conſiſt. Thus the moſt refrangible rays, *i. e.* the red ones, he ſuppoſes to conſiſt of the largeſt particles; the leaſt refrangible, *i. e.* the violet rays, of the ſmalleſt particles; and the intermediate rays, yellow, green, and blue, of particles of intermediate ſizes.

Having given a general view of the Newtonian theory of colours, as they depend upon the refraction of light, under the article COLOUR, we ſhall here add ſome farther particulars on this ſubject. From a review of that article, and of what has been above delivered, we may infer that, as the rays of light differ in refrangibility, they alſo differ in their diſpoſition to exhibit this or that particular colour; ſo that colours are not modifications of light, derived from refractions or reflections of natural bodies, but original and connate properties, which are different in different rays. Moreover, to the ſame degree of refrangibility always belongs the ſame colour, and to the ſame colour the ſame degree of refrangibility; nor are the ſame ſpecies of colour, and degree of refrangibility, that are proper to any particular kind of rays, ſuſceptible of change by refraction and by reflection of natural bodies, nor by any other cauſe which ſir Iſaac Newton could obſerve. Although a ſeeming tranſmutation of colours may be made by a mixture of different kinds of rays, yet, in ſuch mixtures, the component colours themſelves do not appear; but, by their mutually allaying each other, conſtitute a middle colour: and, therefore, if, by refraction, the different rays be ſeparated, colours will emerge different from that of the compoſition. Thus blue and yellow powders, finely mixed, appear green to the naked eye; and yet the colours of the component particles are not thereby really changed, but only blended: for when they are viewed with a microſcope, they ſtill appear blue and yellow. It appears that there are alſo two ſorts of colours: the one original and ſimple; the other compounded of theſe. The original and primary colours are red, orange, yellow, green, blue, indigo, and a violet purple, and an indefinite variety of intermediate gradations. The ſame colours in ſpecie with thoſe primary ones may be alſo produced by a compoſition: thus a mixture of yellow and blue makes green; of red and yellow, orange; and of orange and yellowiſh-green, yellow. In general, if any two colours are mixed, which, in the ſeries of thoſe that are produced by the priſm, are not too far diſtant from one another, they, by their mutual alloy, compoſe that colour which appears in the midway between them; but thoſe which are ſituated at too great diſtance have not this effect: *e. gr.* orange and indigo do not produce the intermediate green, nor ſcarlet and green the intermediate yellow.

The moſt wonderful compoſition is that of whiteneſs, which no one ſort of rays alone can exhibit, but which is always compounded; ſo that all the aforeſaid primary colours, mixed in a certain proportion, are neceſſary to form it. See COLOUR.

Having ſhewn, in the preceding part of this article, the extremes of the different degrees of refrangibility in the different kinds of light, we ſhall now proceed to give the reſult of Newton's inveſtigation, concerning the different degrees of refrangibility of all the different kinds of light, according to their ſeveral colours; particularizing this part of the ſubject with an explanation of the method which he made uſe of to define the boundaries of each colour, in the oblong image of the ſun above deſcribed. In that image, though there was a manifeſt difference of colour, not only between the two extremes, but alſo in the intermediate parts, yet the exact place at which any one colour ended, and another began, was far from being ſufficiently diſtinguiſhable.

guiſhable. The reaſon of this indiſtinctneſs is, that rays of every kind coming from all parts of the ſun's diſc, an entire image of the ſun is projected on the paper, conſiſting of a circle of each particular colour; and as the rays differ in kind by infiniteſimal degrees, from the extreme red to the extreme violet, there muſt, in fact, be thouſands of theſe circles in the ſame oblong image, the centres of which are infinitely near to one another; ſo that the light is intimately mixed, eſpecially in the middle of the image, where it is the brighteſt.

If theſe circles, as he obſerves, whilſt their centres keep their diſtances and poſitions, could be made leſs in diameter, their interfering one with another, and conſequently the mixture of heterogeneous rays, would be proportionably diminiſhed. Thus, in P T, (*fig.* 10.) the circles of which the ſolar image conſiſts, expand into one another; but in the ſame figure, *p t*, being compoſed of leſs circles, but having their centres at the ſame diſtance as the former, do not extend into one another, the mixture being diminiſhed in proportion to the diameters of the circles.

Now theſe circles would be diminiſhed, if, without the room, at a great diſtance from the priſm, towards the ſun, ſome opaque body was placed, having a round hole in the middle of it, to intercept all the ſun's light, excepting ſo much as, coming from the middle of its diſc, could paſs through that hole to the priſm; for ſo the ſeparate circles would no longer anſwer to the whole diſc of the ſun, but only to that part of it which can be ſeen from the priſm, through that hole. But that theſe circles may anſwer more diſtinctly to the hole, a lens is to be placed by the priſm, to caſt the image of the hole, that is, of each ſeparate circle, diſtinctly upon the paper; and if this be done, it will not be neceſſary to place that hole very far off, not even beyond the window. Inſtead, therefore, of that hole, he made uſe of the hole in his window-ſhutter, in the following manner.

At about 10 or 12 feet from the window, he placed a lens, by which the image of the hole might be diſtinctly caſt upon a ſheet of white paper, at the diſtance of 6, 8, 10, or 12 feet from the lens. Then, immediately after the lens, he placed a priſm, by which the refracted light might be thrown upwards, or ſideways; and he moved the paper that received it, either towards the priſm, or from it, till he found the exact diſtance at which the ſides of the image appeared moſt diſtinct. By this means the circular images of the hole were terminated moſt diſtinctly, without any penumbra, and therefore extended into one another the leaſt that they could; and conſequently the mixture of the heterogeneous rays was the leaſt of all. And by uſing a greater or leſs hole in the window-ſhutter, he made the circular images greater or leſs at pleaſure, and thereby the mixture of rays in the oblong image was as much or as little as he choſe. He ſometimes made the breadth of the image 40 times, and ſometimes 60 or 70 times leſs than its length. In this manner, he ſays, light is made ſufficiently ſimple, and homogeneal, for trying any of his experiments about ſimple light; for that the heterogeneous rays in this light are ſo few, as hardly to be perceived, excepting, perhaps, in the indigo and violet, which, being dark colours, do eaſily ſuffer a ſenſible allay by that little ſcattering light, which uſed to be refracted irregularly by the inequalities of the priſm. The whole proceſs of this experiment is ſo evident, by inſpection of *fig.* 11, that it needs no particular illuſtration.

Inſtead of a circular hole, our author recommends a hole ſhaped like a long parallelogram, with its length parallel to the priſm. For if this hole be an inch or two long, and but a 10th or 20th part of an inch broad, or narrower, the light of the image will be as ſimple as before, or more ſimple, and the image will become much broader, and therefore more fit for theſe experiments.

Or, inſtead of this hole, another may be formed of a triangle of equal ſides, whoſe baſe may be about the 10th part of an inch, and its height an inch or more. For, by this means, if the axis of the priſm be parallel to the perpendicular of the triangle, the image *p t* (*fig.* 12.) will now be formed of equicrural triangles, *a g*, *b k*, *c i*, *d k*, *e l*, *f m*, &c. and innumerable other intermediate ones, anſwering to the triangular hole in ſhape and bigneſs, and lying one after another in a continual ſeries, between two parallel lines, *a f*, *g m*. Theſe triangles are a little intermingled at their baſes, but not at their vertices; and therefore the light on the brighter ſide, *a f*, of the image, where the baſes of the triangles are, is a little compounded, but on the darker ſide, *g m*, it is altogether uncompounded; and in all places between the ſides, the compoſition is proportionable to the diſtances of the places from that obſcurer ſide *g m*; and having an image of ſuch a compoſition, we may try experiments either in its ſtronger and leſs ſimple light, near the ſide *a f*; or in its weaker and more ſimple light, near the other ſide *g m*, as ſhall ſeem moſt convenient.

In making theſe experiments, he adviſes, that the chamber be made very dark, that the lens be very good, being made of glaſs free from bubbles and veins, the ſides of the priſm truly plane, and its poliſh elaborate, with an angle of about 65 or 70 degrees; and the edges of the priſm and lens, as far as they make any irregular refraction, ſhould be covered with black paper glued on them. He alſo obſerves, that all the uſeleſs light ſhould be intercepted with black paper, or other black obſtacles. It being difficult to get glaſs priſms fit for theſe nice experiments, he ſometimes uſed priſmatic veſſels made with pieces of broken looking-glaſſes, and filled with rain-water; and to increaſe the refraction, he ſometimes ſtrongly impregnated the water with *ſaccharum ſaturni*.

When he had, by this means, got the ſides of the coloured image, as A F, G M, (*fig.* 13.) diſtinctly defined, he delineated on paper the outlines of it F A P G M T, and held the paper ſo that the image might fall on this figure, and coincide with it exactly; whilſt an aſſiſtant, whoſe eyes could diſtinguiſh colours better than his own, did, by right lines drawn croſs the image, mark the confines of each colour; and this operation being frequently repeated, both on the ſame and on different papers, he found that the obſervations agreed well enough with one another, and that the ſides, M G and F A, were by this means divided like a muſical chord; ſo that if G M were produced to X, making M X equal to G M, and if G X, *l* X, *i* X, *h* X, *e* X, *g* X, *a* X, M X, were in proportion to one another, as the numbers 1, $\frac{8}{9}$, $\frac{5}{6}$, $\frac{3}{4}$, $\frac{2}{3}$, $\frac{3}{5}$, $\frac{9}{16}$, and $\frac{1}{2}$, and ſo repreſented the chords of the key, and of a tone, a third minor, a fourth, a fifth, a ſixth major, a ſeventh, and an eighth above that key. And the intervals M *a*, *a g*, *g e*, *e h*, *h i*, *i l*, and *l* G, were the ſpaces which the ſeveral colours, red, orange, yellow, green, blue, indigo, and violet, took up.

Now theſe intervals or ſpaces, ſubtending the differences of the refractions of the rays, going to the limit of thoſe colours, that is to the points M, *a*, *g*, *e*, *h*, *i*, *l*, G, may, without any ſenſible error, be accounted proportional to the differences of the ſines of refraction of thoſe rays, having one common ſine of incidence; and, therefore, ſince the common ſine of incidence of the moſt and leaſt refrangible rays, out of glaſs into air, was found in proportion to their ſines of refraction as 50 to 77 and 78; if the difference between

tween 77 and 78 be divided, as the line G M is divided by those intervals, there will be 77, $77\frac{1}{8}$, $77\frac{1}{5}$, $77\frac{1}{3}$, $77\frac{1}{2}$, $77\frac{2}{3}$, $77\frac{7}{9}$, 78, for the sines of refraction of those rays out of glass into air, their common sine of incidence being 50. So then the sines of the incidences of all the red-making rays out of glass into air were to the sines of their refractions not greater than 50 to 77, nor less than 50 to $77\frac{1}{8}$; but they varied from one another according to all their intermediate proportions, and so of the other colours.

Having demonstrated that the light of the sun consists of a certain proportion of differently coloured light, our author proves, by another series of experiments, what has been already demonstrated by a single one mentioned above, that when a beam of light has been divided into its component parts, if they be again mixed, they will produce white: or if any one of them be intercepted, the image will appear tinged, and in a different manner, according to the different colours that are thereby prevented from mixing with the rest: and to complete the whole, he observes, that intercepting all the colours that compose the white image except one, and thereby making it to exhibit the appearance of all the colours in order; yet, if he made this succession of all the colours very quick, the appearance was always white, though it was demonstrable that only one colour took place at any one time; and he justly observes, that if each of these colours in succession give the idea of whiteness, much more will they produce that effect, when they are so intimately mixed as they are in a natural sun-beam.

Not content with composing whiteness from the separately coloured rays of the sun, he attempted, and succeeded in his attempt, to do the same with natural coloured bodies, observing the same proportions of the respective colours that he had found in the solar image. The coloured powders which he made use of at first produced only a kind of grey; but this was in fact a dull white, or whiteness mixed with shade: for when he contrived to throw a very strong light upon it, it became intensely white, so that a friend of his, who happened to call upon him while he was busy about these curious experiments, and who knew nothing of what he had been doing, pronounced that the powders he had been mixing, when thus illuminated, made a better white than some very fine white paper, with which he was comparing it.

As the preceding proportion of all the prismatic colours makes a white, it is evident that when they are mixed in different proportions, or when only a few of them are used, they will make different colours; and our philosopher has given us the following ingenious method of knowing, in a mixture of primary colours, the quantity and quality of each being given, the colour of the compound. With the centre O, (*fig.* 14.) and the radius O D, describe a circle A D F, and divide the circumference into seven parts, proportional to the seven musical tones or intervals contained in an octave, that is in proportion to the numbers $\frac{1}{9}$, $\frac{1}{16}$, $\frac{1}{10}$, $\frac{1}{9}$, $\frac{1}{10}$, $\frac{1}{16}$, $\frac{1}{9}$. Let the first, D E, represent a red colour, the second, E F, orange, and so of the rest; and let all these colours be supposed to pass gradually into one another. Let p be the centre of gravity of the arc D E, and q, r, s, t, u, x, be the centres of gravity of the other arcs; and about those centres let circles, proportional to the number of rays of each colour in the given mixture, be described. Then find a common centre of gravity of all those circles; and if a line be drawn from the centre of the circle O, through this point, as suppose at z, the point Y, in which it terminates at the circumference, will shew the colour that arises from the mixture; and the line O Z will be proportioned to the fullness or intenseness of the colour, the centre O representing perfect white. But if only two of the primary colours, which in this circle are opposite to one another, be mixed in an equal proportion, the point Z will fall upon the centre O, and yet the colour compounded of those two will not be perfectly white, but some faint anonymous colour; for he could never, by mixing only two primary colours, produce a perfect white. Whether it might be the result of three taken at equal distances in the circumference he could not tell; but he did not much question, but that four or five of them would be sufficient. These, however, as he observes, are curiosities of little or no moment to the understanding of the phenomena of nature, since, in all natural whites, there is a mixture of all kinds of rays. Newton's Optics. Priestley's Hist. of Light and Colours.

For the method of correcting the effect of the different refrangibility of the rays of light in glasses, see ABERRATION and TELESCOPE; see also DISPERSION *of Light.*

REFRANGIBILITY *of Radiant Heat.* See RAYS *of Heat.* Radiant heat, as well as light, is not only refrangible, but it is also subject to the laws of the dispersion, arising from its different refrangibility. The prism refracts radiant heat, so as to separate that which is less efficacious from that which is more so. The whole quantity of radiant heat contained in a sun beam, if this different refrangibility did not exist, must inevitably fall uniformly on a space equal to the area of the prism; and if radiant heat were not refrangible at all, it would fall upon an equal space, in the place where the shadow of the prism, when covered, may be seen. But neither of these events taking place, it is evident that the radiant heat is subject to the laws of refraction, and also to those of the different refrangibility of light. Whence Dr. Herschel is led to surmise, that radiant heat consists of particles of light of a certain range of momenta, which range may extend a little farther, on each side of refrangibility, than that of light. (See RAYS *of Heat.*) Dr. Herschel having found that two degrees of heat were obtained from that part of the prismatic spectrum which contained the violet rays, while the full red colour, on the opposite side, gave no less than seven degrees, infers from these facts the different refrangibility of the rays which occasion heat, as clearly and certainly as it is concluded that the refrangibility of light is ascertained by the dispersion and variety of the colours. But he proceeds farther, and observes, that the rays of heat are of a much more extensive refrangibility than those of light. In order to make this appear, he delineates a spectrum of light, by assuming a line of a certain length; and, dividing it into seven parts, according to the dimensions assigned to the seven colours by sir Isaac Newton, in the fourth figure of the second part of his Optics, represents the illuminating power of which each colour is possessed, by an ordinate drawn to that line. And here, as the absolute length of the ordinates is arbitrary, provided they be proportional to each other, he assumes the length of that which is to express the maximum, equal to $\frac{27}{33}$ of the whole line.

Thus, let G Q (*fig.* 15.) represent the line that contains the arrangement of the colours, from the red to the violet. Then, erecting on the confines of the yellow and green the line L R $=\frac{27}{33}$ of G Q, it will represent the power of illumination of the rays in that place. For, by experiments already delivered, we have shewn that the maximum of illumination is in the brightest yellow or palest green rays. From the same experiments we collect, that the illuminations of yellow and green are equal to each other, and not much inferior to the maximum; this gives us the ordinates K and M. Then, by the rest of the same experiments, we obtain also the

the ordinates H, I, N, O, P, with fufficient accuracy for the purpofe here intended. All thefe being applied to the middle of the fpaces which belong to their refpective colours, we have the figure G R Q G, reprefenting what may be called the fpectrum of illumination.

We are now, in the fame manner, to find a figure to exprefs the heating power of the refracted prifmatic rays, or what may be called the fpectrum of heat. In order to determine the length of the bafe, Dr. Herfchel examined the extent of the invifible rays, and found, that at a diftance of two inches beyond vifible red, his thermometer, in a few minutes, acquired $1\frac{1}{4}$ degree of heat. The extent of the coloured fpectrum at that time, or the line which anfwered to G Q in his figure, meafured 2.997 inches. If two inches had been the whole of the extent of the invifible part, it might be ftated to be in proportion to the vifible one as 2 to 3; but we are to make fome allowance for a fmall fpace required beyond the laft ordinate, that the curve of the heating power drawn through it may reach the bafe; and indeed, at $2\frac{1}{2}$ inches beyond vifible red, Dr. Herfchel could ftill find $\frac{1}{2}$ degree of heat. It appears therefore fufficiently fafe, to admit the bafe of the fpectrum of heat A Q, to be to that of the fpectrum of light G Q, as $5\frac{1}{4}$ to 3; or, conforming to the Newtonian figure before mentioned, the bafe of which is 3.3 inches, as $57\frac{3}{4}$ to 33. Now, if we affume for the maximum of heat, an ordinate of an equal length with that which was fixed upon for the maximum of light, it will give us a method of comparing the two fpectra together. Accordingly, Dr. Herfchel has drawn the feveral ordinates B, C, D, E, F, G, H, I, K, L, M, N, O, P, of fuch lengths as, from experiments made on purpofe, it appeared they fhould be, in order to exprefs the heat indicated by the thermometer, when placed on the bafe, at the feveral ftations pointed out by the letters.

A mere infpection of the two figures, which have been drawn as lying upon one another, will enable us now to fee how very differently the prifm difperfes the heat-making rays, and thofe which occafion illumination, over the areas A S Q A, and G R Q G, of our two fpectra! Thefe rays neither agree in their mean refrangibility, nor in the fituation of their maxima. At R, where we have moft light, there is but little heat; and at S, where we have moft heat, we find no light at all!

REFRESHMENT, *Quarters of*. See QUARTERS.

REFRET, *Fr.* the burden of a fong. This word is only to be found in the fecond folio edition of Bailey's Dictionary, 1736. In no French dictionary is there authority for it. Cotgrave, Dict. du Vieux Langage; Trevoux, Dict. de l'Académie; and Gloffaries, have been confulted in vain.

REFRIGERANT, REFRIGERATIVE, in *Medicine*, or *cooling*; from *frigus*, *cold*, an appellation given to fuch remedies as were fuppofed to poffefs a power of cooling the internal parts. Hence all diluents, fuch as ptifan, gruel, and other thin drinks, vegetable and mineral acids, neutral falts, and other fubftances, which are deftitute of ftimulating qualities, and communicate a fenfation of coolnefs to the tongue and throat, have been confidered as refrigerant. As they have no actual power of generating cold in the animal body, the term is fomewhat incorrect; but as it expreffes the oppofite quality to that of ftimulating, which is ufed alfo as fynonimous with *heating*, it is ftill retained, and applied to diet, drink, and medicine of a non-ftimulant quality. In this fenfe, the term is nearly fynonimous with *fedative*.

Whatever, in fact, increafes the circulation, increafes the heat of the body, and *vice verfâ*; potentially, therefore, all fedative medicines may be faid to be refrigerant. The ufe of refrigerants will thence be inferred to be proper in all thofe cafes in which there is an over-excitement of the circulation, either locally or generally; fuch as local inflammations, febrile difeafes, hæmorrhages, and the like. In the cafe of external inflammations, indeed, actual refrigeration may be produced, by the application of cold fubftances, water or ice, or by the abftraction of heat by means of evaporation; both of which afford the means of directly diminifhing the activity of the veffels of the part. Thus, in burns and fcalds, the pain is inftantly relieved, and the inflammation effectually reduced, by the immerfion of the part in cold water, if fufficiently perfevered in. But in refpect to internal refrigerants, their operation is of a negative kind, and confifts rather in the removal of uneafy fenfations, and in the exclufion of ftimulant fubftances, than in the actual fuppreffion of increafed action. See SEDATIVE.

REFRIGERATION, denotes the act of cooling, or the abftraction of heat from various fubftances. This is effected in a variety of ways, and for various purpofes of domeftic ufe and of art; and the degree of cold that is produced is eftimated by an inftrument called the *thermometer*, which fee. Under this head it is needlefs to repeat the principles of refrigeration, and the different proceffes that are ufed for this purpofe, which are amply ftated and defcribed under the articles COLD, CONGELATION, COOLING, FREEZING, HEAT, ICE, ICE-*houfes*, &c.

REFRIGERATORY, REFRIGERATORIUM, in *Chemiftry*, a copper veffel filled with cold water, foldered round the capital of an alembic, to cool and condenfe the vapours raifed thither by the fire, and to convert them into a liquor, to be difcharged thence through the beak. See ALEMBIC.

The water in the refrigeratory is to be changed from time to time, as it begins to grow warm.

Sometimes they content themfelves with wrapping a wet cloth about the head of the alembic, inftead of a refrigeratory; but the more ufual method now is, to fupply the place of the refrigeratory by a worm, or fpiral pipe, running through a tub of cold water.

Diftillation chiefly confifts in evaporation and refrigeration. See DISTILLATION.

REFUGE, REFUGIUM, in our *Old Cuftoms*, a *fanctuary*, or *afylum*; which fee refpectively.

At Paris there is an hofpital called the *Refuge*, in which diffolute women are fhut up.

REFUGE, *Cities of*, in *Scripture Hiftory*, fix cities felected from the 48 appropriated to the refidence of the Levites, which were appointed for the protection of perfons from the rigour of the law, who were chargeable with involuntary homicide. Some have fuppofed that all the cities of the Levites were afyla; but it appears from Numb. xxxv. 6. that only fix of them were appointed to this ufe. Thefe afyla were intended not only for Jews, but for Gentiles, or for ftrangers who dwelt among them. (Numb. xxxv. 15.) They were not defigned as fanctuaries for wilful murderers and all forts of atrocious villains among the Jews, as they were among the Greeks and Romans, and as fuch places have fince been in Roman Catholic countries, but merely for fecuring thofe who had been guilty of involuntary homicide (Deut. xix. 4—10.) from the effects of private revenge, until they were cleared by a legal procefs. It is obfervable, that the Ifraelites are commanded to "prepare the way," that is, to make the road good, "that every flayer may flee thither," without impediment, and with all expedition. (Deut. xix. 3.) By having good roads to them, at leaft 32 cubits, or about 48 feet in breadth, and bridges wherever

wherever they were neceſſary, theſe cities were to be eaſy of acceſs; and at croſs roads poſts were erected with inſcriptions, directing the way to the "city of refuge." Upon this Hottinger remarks, that it was probably in alluſion to this cuſtom, that John the Baptiſt is deſcribed as "the voice of one crying in the wilderneſs, prepare ye the way of the Lord, make his paths ſtraight." (Luke, iii. 4—6.) He was the Meſſiah's forerunner, and in that character was to remove the obſtacles to men's flying to him as their aſylum, and obtaining σωτηριον τȣ θεȣ, the ſalvation of God. Every year, on the 15th of Adar, (February,) the magiſtrates were to inſpect the roads, and aſcertain their good condition. Theſe cities were to be ſupplied with water and proviſions; but they were not to be the reſidence of any artiſts who made weapons, by the uſe of which the relations of the deceaſed might gratify their revenge. It was neceſſary that thoſe who took refuge in theſe places ſhould underſtand ſome occupation, that might prevent their being chargeable, whilſt they were waiting for their trial. In order to excite and maintain the greater horror even of involuntary bloodſhed, the law puniſhed it by a kind of baniſhment, for the accuſed perſon was to remain in this city, without departing from it, till the death of the high-prieſt, but after the high prieſt's death, he might ſafely go wherever he pleaſed.

REFUGEES, French Proteſtants, who, by the revocation of the edict of Nantes, in 1685, have been conſtrained to quit their country, and retire for refuge into Holland, Germany, England, &c. to ſave themſelves from the neceſſity of abandoning their religion.

REFUGIO, El, in *Geography*, a harbour in one of the iſlands of Mayorga, where Maurelle was ſupplied with water in 1781, and which, he ſays, affords ſhelter from the moſt furious winds. S. lat. 18° 36′. E. long. 177° 32′.

REFVINGE, a town of Sweden, in the province of Halland; nine miles N.N.W. of Helmſtad.

REFUSAL, in *Law*, is where one hath by law a right and power of having or doing ſomething of advantage to him, and he declines it. An executor may refuſe an executorſhip: but the refuſal ought to be before the ordinary; if an executor be ſummoned to accept or refuſe the executorſhip, and he doth not appear upon the ſummons and prove the will, the court may grant adminiſtration, &c. which ſhall be good in law till ſuch executor hath proved the will; but no man can be compelled to take upon him the executorſhip, unleſs he hath intermeddled with the eſtate. (1 Leon. 154. Cro. Eliz. 858.) Where there are ſeveral executors, and they all refuſe, none of them ſhall adminiſter afterwards; but if there is a refuſal by one, and the other proves the will, the refuſing executor may adminiſter when he will, during the life of his co-executor. (1 Rep. 28.) If there is but one executor, and he adminiſters, he cannot refuſe afterwards, and if once he refuſe, he cannot adminiſter afterwards.

There is a refuſal of a clerk preſented to a church, for want of literature, &c. and if a biſhop once refuſes a clerk for inſufficiency, he cannot accept of him afterward, if a new clerk is preſented. (5 Rep. 58. Cro. Eliz. 27.) In action of trover and converſion, a demand of the goods, and refuſal to deliver them muſt be proved, &c. 10 Rep. 56.

REFUTATION, Refutatio, in *Rhetoric*, that part of the anſwer made to an opponent, which diſproves what had been advanced by him.

REGA, in *Geography*, a river of Pomerania, which riſes three miles N.W. of Dramburg, paſſes by Regenwalde, Plate, Grieffenberg, Treptow, &c., and then runs into the ſea, 12 miles S.W. of Colberg.

REGAH, a town of Egypt, on the left bank of the Nile; ſix miles N. of Atſieh.

REGAL, Regius, or *Regalis*, ſomething belonging to a king. Regal is of the ſame import with royal; the former being formed of the Latin *rex;* the other of the French *roy, king.*

Regal, Fr., a muſical term, which the Encyclopédie defines, "*firſt*, an ancient inſtrument compoſed of many ſticks of ſonorous wood of different lengths, forming a ſcale, played upon by an ivory ball faſtened to the end of a ſtick." This is exactly the deſcription of the ſticcado, ſaid to be invented by the brother of Bremner, the late muſicſeller in the Strand, who publiſhed a book of inſtructions for playing upon it.

"Regal is, *ſecondly*, a ſpinet organized, or rather a ſmall organ of two or three ſtops placed under a keyed inſtrument, very common in Spain and Italy. In France this kind of inſtrument is called a *poſitif*." Craing, an organbuilder in London about the middle of the laſt century, furniſhed organs of this kind to many harpſichords and ſpinets in a virginal form. Snetzler, when he firſt came hither from Straſburg, was employed by Shudi to organize his harpſichord.

But regal in all Roman Catholic countries is a portable organ uſed in proceſſions, carried by one perſon and played by another. We have ſeen that uſe made of this kind of organ at Naples. The pipes are of reeds, for the lightneſs of carriage.

In the liſt of Edward VI. and queen Elizabeth's muſical eſtabliſhments in the Sloane MSS. at the Britiſh Muſeum, among the inſtrument-makers, the regal-maker is allowed 20*l.* yearly. And in our own memory there was an office in the chapel royal under the title of "tuner of the regals;" but it was aboliſhed, and united to ſome more uſeful officer in the chapel.

In the ſupplement to the folio Encyclopédie, we are told that the regal is a portable organ, which has no pipes, or at moſt ſuch as are very ſhort, the tones being produced by reeds. This we believe to be the truth. The inſtrument is ſometimes ſo ſmall as to be ſet on a table.

Regal *Fiſh*. See Royal *Fiſh*.

Regal *Suit*. See Suit.

REGALE, in the French *Juriſprudence*, is a right belonging to the king over all benefices in that kingdom.

The regale conſiſts in enjoying the revenues of biſhoprics, during the vacancy of their ſees, and of preſenting to the benefices dependent on them, which become vacant during that time, and till ſuch a ſucceſſor have taken the oath of fidelity, and have procured letters patent, to ſecure him from the regale.

The enjoyment of the fruits of the ſee is called the *temporal* regale; that of preſenting the benefices, the *ſpiritual* regale.

Some refer the origin of the regale to the time of Clovis; and ſay, the clergy granted this privilege to the king upon his defeating the Viſigoths; others allege, that pope Hadrian I. gratified Charlemagne with it, in a council held at Rome. It is obſerved by others, that the regale was originally no more than a ward, or adminiſtration; and that the kings were only depoſitaries of the fruits of the vacant biſhoprics; and appointed œconomi to look to them during the vacancy.

It is added, that the kings of the firſt and ſecond race never enjoyed any ſuch privilege; and that it was only introduced in the twelfth century, in favour of inveſtitures.

Whatever was the origin of the regale, it occaſioned a very

very important and warm debate between Lewis XIV. and pope Innocent XI. which began about the year 1678, and was carried on with great animofity and contention for feveral years after. Lewis was defirous, that all the churches in his dominion fhould be fubject to the regale. Innocent pretended, on the contrary, that his claim could not be granted with fuch univerfality; nor would he confent to any augmentation of the prerogatives of this nature that had formerly been enjoyed by the kings of France. Lewis fummoned, for fettling this difpute, the famous affembly of thirty-five bifhops, and as many deputies of the fecond order, which met at Paris in the year 1682, and which extended the regale to all the churches in France, without exception. In this convocation the ancient doctrine of the Gallican church, that declares the power of the pope to be merely fpiritual, and alfo inferior to that of a general council, was drawn up in four propofitions, which were folemnly adopted by the whole affembly, and were propofed to the whole body of the clergy, and to all the univerfities through the kingdom, as a facred and inviolable rule of faith.

Regale, *Regalia*, a magnificent treat, or entertainment, given to ambaffadors, or other perfons of diftinction, to entertain or do them honour.

In Italy it is ufual at the arrival of any traveller of eminence, to fend him a regale, that is, a prefent of fruits, fweetmeats, &c. by way of refrefhment.

REGALIA, in *Law*, the royal rights or prerogatives of a king.

Thefe are reckoned by civilians to be fix. 1. Power of judicature. 2. Power of life and death. 3. Power of war and peace. 4. Mafterlefs goods, as waifs, eftrays, &c. 5. Affeffments. 6. Minting of money.

Regalia is alfo ufed for the feveral parts of the apparatus of a coronation: as the crown, the fceptre with the crofs, fceptre with the dove, St. Edward's ftaff, four feveral fwords, the globe, and the orb with the crofs, &c. ufed at the coronation of our kings.

Regalia *of the Church*, are thofe rights and privileges which cathedrals, &c. enjoy by grants, and other conceffions of kings.

Regalia is fometimes alfo ufed for the patrimony of a church; as, *regalia Sancti Petri*. And more particularly, for fuch lands and hereditaments as have been given by kings to the church.

"Cæpimus in manum noftram baroniam et regalia quæ archiepifcopus Eborum de nobis tenet." Pryn. Lib. Ang.

Thefe regalia, while in poffeffion of the church, were fubject to the fame fervices as all other temporal inheritances; and after the death of the bifhop they reverted to the king, till he invefted another with them; which, in the reigns of William the Conqueror, and fome of his immediate fucceffors, was frequently delayed, and as oft did the bifhops make complaint of it, as appears from Malmfbury, Neubrigenfis, &c.

This laft author fays, that great complaint was made againft Henry II. "Quod epifcopatus vacantes, et provenientia perciperet commoda, diu vacare voluit, et ecclefiafticis potius ufibus applicanda in fifcum redegit."

Regalia *Facere* is ufed for the bifhop's doing homage, or fealty, to the king, when he is invefted with the regalia. Thus Malmfbury, in Anfelm: "Regalia pro more illius temporis faciens principi vii. kalend. Octobris Cantuariæ affedit."

REGALITIES. See Royalties.

REGAN, in *Geography*, a town of Perfia, in the province of Kerman, and diftrict of Nurmanfheer, on the frontier of Kerman to the eaft, which diftrict is about 90 miles in length, and in breadth from 30 to 80. This diftrict is bounded on the N. and S. by a range of mountains, thofe to the S. being covered with fnow during the greater part of the year. The foil is fertile, the diftrict populous, and well watered by ftreams from the mountains, and the climate hot in the plain, but cold on the mountains. The Afghans were lately expelled from this diftrict by the Perfians, who invited different tribes of Balouches to occupy the deferted villages.

Regan is a neat little town, furrounded by a mud wall, within which the cattle of the inhabitants are driven every night for protection. The fort is quadrangular, the walls high and in good repair, and flanked with baftions; with one gate, conftantly guarded for preventing the entrance of ftrangers. The capital of Nurmanfheer is Krook, which is the refidence of the governor, and built in the fame ftyle as Regan, but larger, and furrounded by a deep ditch. Before the expulfion of the Afghans, a city, called Bumm, was confidered as the frontier town of Perfia in this quarter. This city is ftrongly fortified by a high mud wall, flanked with towers, furrounded by a deep and broad dry ditch, with one gate; and it has a bazar tolerably fupplied with dates, milk, and fruit. The ruins of Bumm teftify that it was formerly of much greater extent than it is at prefent. The fountains are faid to have thrown water to an amazing height, and the gardens, which appear to have been walled in, and adorned with elegant fummer-houfes, produce the moft delicious pomegranates. Kinneir's Geog. Memoir of the Perfian Empire, 1813.

REGARD *of the Foreft*, the overfight, or infpection, of it; or the office and province of the regarder; which is, to go through the whole foreft, and every bailiwick of it, before the holding of the feffions of the foreft, or juftice-feat, to fee and enquire of the trefpaffes in it, and for the furvey of dogs. A court for this purpofe is to be holden every third year. See Expeditation, and Forest.

"Ad vivendum, ad inquirendum, ad certificandum, &c." See Regarder.

Regard is alfo ufed for the extent of the regarder's charge, *i. e.* for the whole foreft; or all the ground that is parcel of it.

REGARDANT, in *Heraldry*, is underftood of a lion, or other beaft of prey, borne in a pofture of looking behind him, with his face towards his tail.

Others apply it to a beaft, which only fhews the head, and fome part of the neck, as moving from out of fome divifion of the coat into another. He bears azure, three bends, or, in a chief, argent, charged with a lion regardant, gules.

Regardant *Villain*, or *Regardant to the Manor*, denotes an ancient fervant or retainer to the lord; thus called, becaufe charged to do all bafe fervices within the manor, to fee the fame freed of all filthy and loathfome things that might annoy it, &c. Coke upon Littleton, fol. 120.

REGARDER *of a Foreft*, *Regardator Forefta*, an ancient officer of the king's foreft, whofe bufinefs was every year, upon oath, to make a regard, *i. e.* to take a view of the foreft limits; alfo to enquire of all offences and defaults committed by the forefters within the foreft, and of all the concealments of them; and whether all the other officers did execute their refpective duties or not.

Manwood refers this inftitution to king Henry II. but Spelman thinks the name, at leaft, was given fince; and that they were the fame with thofe officers called *cuftodes venationis*.

REGATTA

REGATTA is a name given at Venice to a kind of exhibition on the water, in which the gondoliers conteft for fuperiority in the art of rowing their gondolas.

A fplendid entertainment, under this appellation, was exhibited on the Thames in 1775.

REGAU, in *Geography*, a town of Auftria; 12 miles W. of Steyr.

REGE INCONSULTO, in *Law*, is a writ iffued from the king to the judges, not to proceed in a caufe which may prejudice the king, until he is advifed. A *rege inconfulto* may be awarded, not only for the party to the plea, but upon fuggeftion of a ftranger, on caufe fhewn that the king may be prejudiced by the proceeding, &c.

REGE *Querela Coram*. See QUERELA.

REGEL, or RIGEL, in *Aftronomy*, a fixed ftar of the firft magnitude, in Orion's left foot.

REGELSBRUN, in *Geography*, a town of Auftria; feven miles N. of Brugg.

REGEN, a river which rifes on the borders of Bohemia, and runs into the Danube, near Ratifbon.—Alfo, a town of Bavaria, on the above-named river; 40 miles E. of Ratifbon.

REGENERATED TARTAR. See TARTAR, *Regenerated.*

REGENERATION, in *Theology*, the act of being born again by a fpiritual birth, or becoming a child of God: or it is that change of heart and life experienced by a perfon, who forfakes a courfe of vice, and fincerely embraces a life of piety and virtue.

When an infidel is converted, baptifm is always adminiftered as a fign of regeneration.

The term is alfo ufed to fignify the change of ftate that takes place at the refurrection. Matt. xix. 28.

REGENSBERG, in *Geography*, a town of Switzerland, in the canton of Zurich, fituated on a mountain, and furrounded with walls in the year 1687; it is the principal place of a bailiwick formerly fubject to the dukes of Auftria; 6 miles E. of Baden.

REGENSBURG. See RATISBON.

REGENSTAUF, a town of Bavaria, in the principality of Neuburg; feven miles N. of Ratifbon.

REGENSTEIN, a town of Weftphalia, in the bifhopric of Halberftadt; feven miles W. of Quedlinburg.

REGENSTORF, or *Old Regenfberg*, a bailiwick of Switzerland, in the canton of Zurich, which derives its name from that of an ancient caftle, deftroyed in 1443.

REGENT, REGENS, a perfon who governs a kingdom during the minority or abfence or incapacity of a king.

In France, the queen-mother has the regency of the kingdom, under the title of *queen-regent*, while the king is a minor. Some have urged, that women, being incapable of fucceeding to that crown, were incapable of the regency; but cuftom has declared in their favour.

REGENT is alfo ufed for a profeffor of arts and fciences, who holds a clafs, or fet of pupils, in a college.

The foreign univerfities are generally compofed of doctors, profeffors, and regents. Regent and fcholar are relative terms. See TUTOR.

Regent is generally reftrained to the lower claffes, as regent of rhetoric, regent of logic, &c.; thofe of philofophy are rather called profeffors.

REGENWALDE, in *Geography*, a town of Hinder Pomerania, on the Rega; 30 miles N.N.E. of Stargard. N. lat. 53° 49'. E. long. 15° 24'.

REGERENDARIUS, among the Romans, an officer who fubfcribed and kept a regifter of all petitions prefented to the præfect. Pitifc. in voc.

REGESTOLA, in *Ornithology*, a name ufed by fome authors for the mattagefs, or larger butcher-bird, a very fmall hawk, not exceeding the fize of a common thrufh, but very fierce and voracious. See LANIUS *Excubitor.*

REGETZ, in *Geography*, a town of Hungary; 18 miles S. of Cafchau.

REGGE, a river of Holland, which rifes near Enfchede, and after paffing by Ghoer, Ryfen, &c. joins the Vecht near Ommens.

REGGIO, PIETRO, in *Biography*, a native of Genoa, who feems to have been the firft Italian who gave our country a tafte for the vocal refinements of his country. Before his arrival here, he had been in Spain, Germany, Sweden, and France. Befides refinements in florid fong, he was much admired for his exquifite manner of accompanying himfelf on the lute. His firft refidence in England was at Oxford, where he publifhed, in 1677, a fmall tract, entitled "A Treatife to fing well any fong whatever." In 1684 his book of fongs, in folio, the words chiefly from Cowley, appeared. We know not what were the tafte and expreffion which rendered his vocal powers fo captivating; but his airs are very dry and monotonous, and in as old an Italian tafte as thofe of Lulli.

REGGIO, in *Geography*, a city of Italy, capital of the department of the Croftolo, and formerly of the duchy of Modena, the fee of a bifhop, fuffragan of Bologna. It was founded by the Tufcans, and became a Roman colony under Lepidus the triumvir. It was deftroyed by Alaric, and rebuilt by Charlemagne. Its number of convents is 16, and of inhabitants about 18,000. The cathedral contains many capital pictures and fculptures. The inhabitants of this city were the firft of all the Italians, who in 1794 renounced their allegiance to their own fovereign, Hercules III., who fled to Venice, afterwards took up arms, and folicited the protection of Bonaparte. He took poffeffion of the city, proclaimed the liberty of the inhabitants, and inftituted a legiflative committee, who took the oath of allegiance to the French republic. Reggio is the native place of the poet Ariofto; 14 miles W.N.W. of Modena. N. lat. 44° 41'. E. long. 10° 38'.

REGGIO, a fea-port town of Naples, in Calabria Ultra, fituated on the ftraits of Meffina. The inhabitants carry on manufactures of ftockings, gloves, and waiftcoats of thread or filk. This place is the fee of an archbifhop, founded by the patriarch of Conftantinople, and contains two colleges and feven convents. The environs abound in oranges, citrons, mulberries, and grapes, with fome fugar-canes. This town was called by the Greeks *Rhegion*, derived according to Diodorus from the Greek word ῥήγνυμι, to break or tear, becaufe Sicily was torn from Italy, either by the fea or an earthquake. It is very ancient, founded as fome fay by Jocaftrus, fon of Æolus, king of Lipari, who entertained Ulyffes; or, according to others, by the Chalcidians, who came hither from Eubœa. The territory of the Rhegini was free and powerful, though fometimes governed by tyrants. In the Peloponnefian war they fuffered much from their neighbours the Epizephyrian Locri, and were diftracted by internal contentions. In the time of Dionyfius the elder they were very powerful and afferted their liberty, refufing an alliance with that tyrant, who demanded a daughter of the city. When Pyrrhus waged war againft the Romans, the latter fent a legion for the protection of Rhegium; but the foldiers murdered the citizens and feized on the city. After the war the infurgents were taken by the Romans, and put to death for their treachery and cruelty. St. Paul, on his journey to Rome, paffed through this city. In the year 1783 it was almoft totally deftroyed by by an earthquake; 10 miles S.E. of Meſſina. N. lat. 38° 6'. E. long. 16° 53'.

REGGIOLO, a town of Italy, in the department of the Mincio; ſix miles E. of Guaſtalla.

REGHABILLE, a town of Africa, in the country of Wangara, ſituated on a lake. N. lat. 12° 47'. E. long. 18° 19'.

REGIA AQUA. See AQUA.

REGIA *Via*. See VIA.

REGIA *Villa*. See VILLA.

REGICIDE, REGICIDA, *a king-killer*. The term is alſo uſed for the act itſelf of murdering a king; of *rex*, *king*, and *cædo*, *I ſlay*.

Regicide is chiefly uſed with us in ſpeaking of the perſons concerned in the trial, condemnation, and execution, of king Charles I.

REGIFUGE, REGIFUGIUM, a feaſt held in ancient Rome on the ſixth of the calends of March, *i. e.* on our 24th of February, in memory of the expulſion of their kings, particularly of Tarquin's flying out of Rome on that day. Some will have the feaſt to bear this name from the *rex ſacrorum*, *king of the ſacrifices*, flying out of the comitia, or place of aſſembly, as ſoon as the ſacrifice was over, in imitation of the flight of Tarquin the Proud.

Some critics and antiquaries will have Regifugium the ſame with Fugalia; others hold them to be different.

REGIMEN, in *Medicine*, from *rego*, *I rule* or *govern*, a rule or courſe of living, with regard to eating, drinking, clothing, and the like, accommodated to ſome diſeaſe, or particular courſe of medicine which the patient is under, or intended as a prevention of ſome threatening malady.

In many diſeaſes, eſpecially thoſe of the acute or febrile claſs, the regimen is often of equal, and ſometimes of more importance than medicine: and there can be no doubt that the humoral phyſicians, by the introduction of a *hot* regimen in the treatment of febrile complaints, contributed to render theſe diſeaſes more ſevere and fatal; and that the ſubſtitution of a cool regimen has of late years very materially diminiſhed the danger and mortality of theſe maladies. This change in medical practice has been, in fact, but a return to nature, and to Hippocrates, who taught this ſimple, but clear and rational principle, "contraria contrariis medentur;" remedies ſhould be of an oppoſite nature to diſeaſes: that is to ſay, if the body is morbidly hot, cold is the remedy; if it is cold, the application of heat is neceſſary; if there is over-diſtention, inflammation, or plethora, evacuation muſt be reſorted to: if depletion, we muſt ſupply nouriſhment: if there is thirſt, the remedy is the free uſe of drink, and ſo forth. The clear inſtincts of nature (where they can be diſtinguiſhed) are commonly infallible guides, as to the regimen to be purſued: but let not morbid habits and prejudices be miſtaken for them. Thus in *all fevers*, ſmall-pox, meaſles, ſcarlet-fever, catarrh, typhus, and the plague itſelf, the natural bias is for freſh air, coolneſs, light bed-clothes, clean linen, cold drink, light and merely liquid nouriſhment, in ſmall quantities, or abſolute abſtinence, quietneſs of mind and body, relief from noiſe, ſtrong light, and every ſpecies of excitement; and this is preciſely the regimen, which experience has proved to be moſt beneficial in ſuch diſeaſes. Under the influence of ſuch a regimen, where proper medicines are alſo employed, every ſymptom is rendered comparatively mild; the diſtreſs of the ſick is diminiſhed, by the ſoothing of every morbid ſenſation; and the derangements, which would otherwiſe enſue, or be aggravated, in the more vital organs, as in the brain, lungs, and alimentary canal, are frequently altogether prevented.

It is ſufficient to contraſt the effects of the hot regimen, in febrile diſeaſes, to be convinced of the truth of theſe obſervations. When a perſon afflicted with any ſpecies of fever, is confined in a cloſe and heated apartment, in which the free circulation of air is prevented by cloſed doors and windows, curtains, &c. and is kept at the ſame time under a load of bed-clothes, and ſupplied with hot drinks, or even cordials of vinous and fermented liquors, with the view of inducing perſpiration, the conſequences are as follow. The whole train of ſymptoms is aggravated. The heat of the patient is raiſed conſiderably above the natural ſtandard, notwithſtanding the profuſe perſpirations that are conſtantly bathing him; the pulſe is excited to the higheſt febrile ſtandard; the thirſt becomes inceſſant to ſupply the unnatural waſte of fluids; the mouth and lips become parched and furred; the head is in conſtant pain, with confuſion of ideas, preventing all ſound ſleep, and occaſioning diſtreſſing dreams, and at length delirium; the whole powers of the frame become proſtrate, with diſpoſition to fainting, on being moved, or on paſſing an evacuation by ſtool; and from this ſituation the recovery is extremely precarious. In caſes of contagious fever, ſuch as ſmall-pox, meaſles, ſcarlet-fever, &c., the eruption is always greatly multiplied by this hot regimen, and all the ſymptoms are changed to what has been called a putrid type; the tongue, teeth, and lips, become coated with a black, clammy, and immoveable fur; purple ſpots appear on the ſkin; and the whole diſeaſe aſſumes the character of malignancy. There is one diſeaſe, indeed, which is ſolely the reſult of this hot regimen, which has made a conſiderable figure in the writings of phyſicians, who never dreamt that it was of their own creation; we allude to the *miliary* fever. See MILIARIA.

The above may perhaps be conſidered as the extreme of the picture, which is ſcarcely ever to be ſeen in the preſent day. But the greateſt difficulty which a phyſician has even now to overcome, in the majority of caſes of feveriſh diſeaſes, is to counteract the tendency of nurſes and parents to the adoption of more or leſs of this pernicious ſyſtem. The ſalutary *chill* muſt be taken away from all liquids, whether uſed internally or externally; the cheering breeze is deemed a death-bringing *draught*; and though the patient may die from the ſeverity of a malignant fever, he muſt on no account run the ſlighteſt riſk of *catching cold*; that is to ſay, the poſſible occurrence of a ſlight ſore-throat, or a running at the noſe, is to be avoided religiouſly, at the expence of aggravating both the ſufferings and the danger, under a more formidable diſeaſe. The uſe of wine and cordials, in theſe diſeaſes, is now confined to the poor and ignorant, and it is to be hoped, that the other parts of the hot regimen will not long be reſorted to, at leaſt among the more intelligent claſſes of ſociety. See COLD *as a remedy*.

REGIMEN, in *Chemiſtry* and *Alchemy*, is the method of ordering and conducting any thing, that it may anſwer its intention.

Thus, regimen of fire is the method of making and ordering fire, and the degrees of it.

REGIMEN *of the Work*, that is, of the philoſopher's ſtone, called the *work of patience*, is the rule and conduct to be obſerved to obtain protection.

There are three things, they ſay, to be chiefly regarded in the regimen of the work. The firſt, to adminiſter a gentle eaſy heat at the beginning of the coction.

The ſecond, to continue this external heat according to the ſeaſon of the work, always obſerving four ſeaſons, as in the common and aſtronomical year; the beginning being the winter, the progreſs the ſpring, then ſummer, and laſtly autumn, which is the time of maturity and perfection of the ſtone;

ftone; in all which the heat is to be augmented in proportion to the augmentation obferved in nature.

It is to be added, that the work may not be begun in any feafon; but regard is to be had to the feafons of nature. left the winter of the work be found in the fummer of the year, &c. Which, however, is to be underftood of the day in which the mercury is put in the ovum philofophicum, not of that when it is begun to be fet at liberty from the prifons which nature had inclofed it in.

The third is, that in augmenting the fire, the augmentation be not of a whole degree at once, the fpirits being unable to bear fuch violence; but a degree is to be divided into four parts, and one part is to be taken at a time.

All the operations of the firft regimen are occult and invifible: in the fecond regimen comes putrefaction, which, they fay, is the firft fenfible change, fhewing itfelf by its black colour.

Regimen, or *Government*, in *Grammar*, is that part of fyntax or conftruction, which regulates the mutual dependency of words, and the alterations which one part of fpeech occafions in another, with regard to its mood, tenfe, or cafe, and thus it differs from concord, or the agreement which one word has with another, in gender, number, cafe, or perfon. See Concord.

The regimen, or government, is entirely arbitrary, and differs in all languages; one language forming its regimen by cafes, as the Latins and Greeks; others by particles in lieu of them, as the Englifh by *of*, *to*, &c. the French, Spaniards, and Italians, by *de*, *a*, *da*, &c.

There are, however, fome general maxims which hold good in all languages; as, 1. That there is no nominative cafe in any fentence but has a reference to fome verb, either expreffed or underftood. Sometimes, indeed, the infinitive mood, or part of a fentence, is put as the nominative cafe to the verb; as in Englifh, "to fee the fun is pleafant." Thefe fentences, or claufes, thus conftituting the fubject of an affirmation, may be termed "nominative cafes."

2. That there is no verb, except in the infinitive mood, or the participle, but has its nominative cafe, either expreffed or underftood. Indeed, in languages which have proper accufatives, as the Latin, before infinitives there is an accufative, not a nominative cafe; as *Scio Petrum effe doctum*. The nominative cafe is commonly placed before the verb; but fometimes it is put after the verb, if it is a fimple tenfe; and between the auxiliary and the verb, or participle, if a compound tenfe.

3. Two or more nouns, &c. in the fingular number, joined together by one or more copulative conjunctions, expreffed or underftood, muft have verbs, nouns, and pronouns, agreeing with them in the plural number. The conjunction disjunctive, however, has an effect contrary to that of the conjunction copulative; for as the verb, noun, or pronoun, is referred to the preceding terms, taken feparately, it muft be in the fingular.

4. A noun of multitude, or fignifying many, may have a verb or pronoun agreeing with it, either of the fingular or plural number; but not without regard to the import of the word, as conveying unity or plurality of idea. In the application of this rule, we ought to confider whether the term immediately fuggefts the idea of the number it reprefents, or whether it exhibits to the mind the idea of the whole as one thing. In the former cafe, the verb ought to be plural; in the latter, it ought to be fingular.

5. Pronouns muft always agree with their antecedents, and the nouns for which they ftand, in gender and number.

6. The relative is the nominative cafe to the verb, when no nominative comes between it and the verb; but when a nominative comes between the relative and the verb, the relative is governed by fome word in its own member of the fentence; *e. gr.* "he *who* preferves me, to *whom* I owe my being, *whofe* I am, and *whom* I ferve, is eternal."

7. When the relative is preceded by two nominatives of different perfons, the relative and verb may agree in perfon with either, according to the fenfe.

8. Every adjective, and every adjective pronoun, belongs to a fubftantive, expreffed or underftood. Adjective pronouns muft agree in number with their fubftantives; neverthelefs this rule admits of exceptions; *e. gr.* the word *means* in the fingular number, and the phrafes "by this means," "by that means," are ufed by our beft and moft correct writers, *viz.* Bacon, Tillotfon, Atterbury, Addifon, Steele, Pope, &c. Campbell, in his "Philofophy of Rhetoric," has this remark on the fubject before us: "No perfons of tafte will, I prefume, venture fo far to violate the prefent ufage, and confequently to fhock the ears of the generality of readers, as to fay 'by this *mean*,' 'by that *mean*.'" Lowth and Johnfon feem alfo to be againft the ufe of *means* in the fingular number. The diftributive adjective pronouns, *each*, *every*, *either*, agree with the nouns, pronouns, and verbs of the fingular number only. Adjectives are fometimes improperly applied as adverbs. An adjective pronoun, in the plural number, will fometimes properly affociate with a fingular noun. Although the adjective always relates to a fubftantive, it is, in many inftances, put as if it were abfolute, efpecially where the noun has been mentioned before, or is eafily underftood, though not expreffed. Subftantives are often ufed as adjectives: in this cafe, the word fo ufed is fometimes unconnected with the fubftantive to which it relates; fometimes connected with it by a hyphen; and fometimes joined to it, fo as to make the two words coalefce. Sometimes the adjective becomes a fubftantive, and has another adjective joined to it. When an adjective has a prepofition before it, the fubftantive being underftood, it takes the nature of an adverb, and is confidered as an adverb.

9. One fubftantive governs another, fignifying a different thing, in the poffeffive or genitive cafe; inafmuch as that cafe always expreffes the poffeffor, which muft be governed by the poffeffed: as, "my father's houfe," "virtue's reward," &c. When the annexed fubftantive fignifies the fame thing as the firft, and ferves merely to explain or defcribe it, there is no variation of cafe; as "George, king of Great Britain, elector of Hanover, &c." Nouns thus circumftanced are faid to be *in appofition* to each other: and nouns are not unfrequently fet in appofition to fentences, or claufes of fentences. This rule does not hold fo apparently in the modern as it does in the ancient languages; becaufe the particles *of*, *de*, &c. which are the proper figns of the genitive cafe, are frequently ufed as prepofitions. (See Genitive.) Subftantives govern pronouns as well as nouns in the poffeffive cafe; as "every tree is known by *its* fruit." Sometimes a fubftantive in the genitive or poffeffive cafe ftands alone, the latter one by which it is governed being underftood. The Englifh genitive has often an unpleafant found, fo that we make more ufe of the particle *of* to exprefs the fame relation: and in fome cafes, we ufe both the genitive termination and the prepofition *of*; as "it is a difcovery of fir Ifaac Newton's:" but when this double genitive, as fome grammarians call it, is not neceffary to diftinguifh the fenfe, and efpecially in a grave ftyle, it is generally omitted. Except to prevent ambiguity, it feems to be allowable only in cafes which fuppofe the exiftence of a plurality of fubjects of the fame kind, as "a fubject of the emperor's." But after all that can be faid for the double genitive, as it is termed,

termed, it is the opinion of some grammarians, that it would be better to avoid the use of it altogether, and to give the sentiment another form of expression.

10. Active verbs govern the objective (or accusative) case, as "Virtue rewards her followers." In English, the nominative case, denoting the subject, usually goes before the verb; and the objective case, denoting the object, follows the verb active; and it is this order that determines the case in *nouns;* as, "Alexander conquered the Persians:" but the *pronoun* having a proper form for each of those cases, is sometimes, when it is in the objective case, placed before the verb; and when it is in the nominative case, follows the object and verb; as "*whom* ye ignorantly worship, *him* declare I unto you." Verbs neuter do not act upon, or govern, nouns and pronouns. Part of a sentence, as well as a noun or pronoun, may be said to be in the objective case, or to be put objectively, governed by the active verb; and sentences or phrases under this circumstance may be termed "objective sentences or phrases." The verb *to be,* through all its variations, has the same case after it as that which next precedes it; so that this substantive verb has no government, or case, but serves, in all its forms, as a conductor to the two cases, insomuch that the two cases which, in the construction of the sentence, are the *next* before and after it, must always be alike. Passive verbs which signify *naming,* and others of a similar nature, have the same case before and after them; as "*he* was called *Cæsar.*" It is evident also, that certain other neuter verbs, besides the verb *to be,* require the same case, whether it be the nominative or the objective, before and after them; such verbs are, to become, to wander, to go, to return, to appear, to die, to live, to look, to grow, to seem, to roam, and several others. The auxiliary *let* governs the objective case; as "let *him* beware."

11. One verb governs another that follows it, or depends upon it, in the infinitive mood; as, "cease *to do* evil," "learn *to do* well;" and the preposition *to,* though generally used before the latter verb, is sometimes properly omitted; as "I heard him say it," instead of "*to* say it." This irregularity extends only to active or neuter verbs: for many other verbs, when made passive, require the preposition *to* before the following verb; as "He was seen *to go.*" The infinitive is frequently governed by adjectives, substantives, and participles; and this mood has much of the nature of a substantive, expressing the action itself which the verb signifies, as the participle has the nature of an adjective, so that the infinitive mood does the office of a substantive, in different cases, as in the nominative, "*to play* is pleasant," and in the objective, "boys love *to play.*" The infinitive mood is often made absolute, or used independently on the rest of the sentence, supplying the place of the conjunction *that* with the potential mood, as "to confess the truth, I was in fault." The preposition *to,* signifying *in order to,* was anciently preceded by *for,* as "what went ye out *for to see;*" but the word *for* before the infinitive, is now, in almost every case, obsolete.

12. In the use of words and phrases which, with respect to time, relate to each other, a due regard to that relation should be observed. Thus, instead of saying, "the Lord *hath given,* and the Lord *hath taken* away," we should say, "the Lord *gave,* and the Lord *hath taken* away." To preserve consistency in the time of verbs, and also of words and phrases, says Mr. L. Murray, in his excellent treatise on Grammar, we must recollect that, in the subjunctive mood, the present and the imperfect tenses often carry with them a future sense; and that the auxiliaries *should* and *would,* in the imperfect time, are used to express the present and future, as well as the past. With regard to verbs in the infinitive mood, says the same popular author, the practice of many writers, among whom are some of the most respectable, appears to be erroneous. They seem not to advert to the true principles which influence the different tenses of this mood. The following rules will, according to our author's judgment, be found perspicuous and accurate. "All verbs expressive of hope, desire, intention, or command, must invariably be followed by the present, and not the perfect of the infinitive." Instead of the phrase, "the last week I intended to *have written,*" though common, the infinitive being in the past time, as well as the verb which it follows, it ought to be, "the last week I intended *to write:*" for how long soever it now is since I thought of writing, "to write" was then present to me, and must still be considered as present, when I bring back that time, and the thoughts of it. Some writers on grammar, however, maintain that the former sentence is correct and grammatical, because, as they assert, it simply denotes the speaker's intention to be hereafter in possession of the finished action of writing; but this reasoning admits of the following answers, according to the statement of Mr. Murray. The phrase "to have written" is, in English grammars, the established past tense of the infinitive mood, and as incontrovertibly the past tense of the infinitive in English, as *scripsisse* is the past tense of the infinitive in Latin; nor can any writers be warranted in taking such liberties with the language, as to contradict its plainest rules, for the sake of supporting an hypothesis. Moreover, these writers might, on their own principles, and with equal propriety, contend, that the phrase "I intended *having written,*" is proper and grammatical; but by admitting such violations of established grammatical distinctions, confusion would be introduced, the language would be disorganized, and the most eccentric systems of grammar might be advanced, and plausibly supported. In short, says our author, the phrase "I intended to have written," appears to involve the following absurdity; "I intended to produce hereafter an action or event, which has been already completed." Some may hastily infer from the rule above stated, and from the near relation between the verbs *to desire,* and *to wish,* that the latter verb, like the former, must invariably be followed by the present of the infinitive. But when any one considers, that the act of *desiring* always refers to the future, and that the act of *wishing* refers sometimes to the past, as well as sometimes to the future, he will perceive the distinction between them, and that, consequently, the following modes of expression are strictly justifiable: "I wished *that I had written* sooner," "I wished *to have written* sooner;" and he will be perfectly satisfied, that the following phrases must be improper: "I desired that I had written sooner," "I desired to have written sooner." Mr. Murray, having considered and explained the special rule, respecting the government of verbs, expressive of hope, desire, intention, or command, proceeds to state and elucidate the general rule, on the subject of verbs in the infinitive mood. "This rule," he says, "is founded on the authority of Harris, Lowth, Campbell, Pickbourn, &c.; and we think, too, on the authority of reason and common sense. "When the action or event, signified by a verb in the infinitive mood, is *contemporary* or *future,* with respect to the verb to which it is chiefly related, the present of the infinitive is required; when it is *not* contemporary, *nor* future, the perfect of the infinitive is necessary." To comprehend and apply this rule, the student has only to consider, whether the infinitive verb refers to a time antecedent, contemporary, or future, with regard to the governing or related verb. When this simple point is ascertained, there will be no doubt in his mind, respecting the

form

form which the infinitive verb should have. A few examples may illustrate these positions. If I wish to signify, that I rejoiced at a particular time, in recollecting the sight of a friend, some time having intervened between the *seeing* and the *rejoicing*, I should express myself thus: "I rejoiced *to have seen* my friend." The *seeing*, in this case, was evidently antecedent to the *rejoicing*; and therefore the verb which expresses the former, must be in the perfect of the infinitive mood. The same meaning may be expressed in a different form: "I rejoiced *that I had seen* my friend;" or, "*in having seen* my friend:" and the student may, in general, try the propriety of a doubtful point of this nature, by converting the phrase into these two correspondent forms of expression. When it is convertible into both these equivalent phrases, its legitimacy must be admitted.—If, on the contrary, I wish to signify, that I rejoiced at the sight of my friend, that my joy and his presence were contemporary, I should say, "I rejoiced *to see* my friend;" or, in other words, "I rejoiced *in seeing* my friend." The correctness of this form of the infinitive may also, in most cases, be tried, by converting the phrase into other phrases of a similar import.

The subject may be still further illustrated, by additional examples. In the sentence which follows, the verb is with propriety put in the perfect tense of the infinitive mood: "It would have afforded me great pleasure, as often as I reflected upon it, *to have been* the messenger of such intelligence." As the message, in this instance, was antecedent to the pleasure, and not contemporary with it, the verb expressive of the message must denote that antecedence, by being in the perfect of the infinitive. If, on the contrary, the message and the pleasure were referred to as contemporary, the subsequent verb would, with equal propriety, have been put in the present of the infinitive: as, "it would have afforded me great pleasure, *to be* the messenger of such intelligence." In the former instance, the phrase in question is equivalent to these words; "*if I had been* the messenger;" in the latter instance, to this expression; "*being* the messenger."

To assert, as some writers do, that verbs in the infinitive mood have no tenses, no relative distinctions of present, past, and future, is inconsistent with just grammatical views of the subject. That these verbs associate with verbs in all the tenses, is no proof of their having no peculiar time of their own. Whatever period the governing verb assumes, whether present, past, or future, the governed verb in the infinitive always respects that period, and its time is calculated from it. Thus, the time of the infinitive may be before, after, or the same as, the time of the governing verb, according as the thing signified by the infinitive, is supposed to be before, after, or present with, the thing denoted by the governing verb. It is, therefore, with great propriety, that tenses are assigned to verbs of the infinitive mood. The point of time from which they are computed is of no consequence; since present, past, and future, are completely applicable to them.

It may not be improper to observe, that though it is often correct to use the perfect of the infinitive after the governing verb, yet there are particular cases, in which it would be better to give the expression a different form. Thus, instead of saying, "I wish to have written to him sooner," "I then wished to have written to him sooner," "He will one day wish to have written sooner;" it would be more perspicuous and forcible, as well as more agreeable to the practice of good writers, to say; "I wish that I had written to him sooner," "I then wished that I had written to him sooner," "He will one day wish that he had written sooner."

13. Participles have the same government as the verbs from which they are derived; as, "I am weary with *hearing him*," &c. It should be considered, however, that participles are sometimes governed by the article; for the present participle, with the definite article *the* before it, becomes a substantive, and must have the preposition *of* after it. This rule arises from the nature and idiom of our language, and from as plain a principle as any on which it is founded; namely, that a word which has the article before it, and the possessive preposition *of* after it, must be a noun; and, if a noun, it ought to follow the construction of a noun, and not to have the regimen of a verb. It is the participial termination of this sort of words that is apt to deceive us, and make us treat them as if they were of an amphibious species, partly nouns and partly verbs.

The same observations, which have been made respecting the effect of the article and participle, appear to be applicable to the pronoun and participle, when they are similarly associated. When a substantive is put absolutely, and does not agree with the following verb, it remains independent on the participle, and is called the "case absolute," or the "nominative absolute;" but when the substantive preceding the participle agrees with the subsequent verb, it loses its absoluteness, and is like every other nominative.

14. Adverbs, though they have no government of case, tense, &c. require an appropriate situation in the sentence, *viz.* for the most part, before adjectives, after verbs active or neuter, and frequently between the auxiliary and the verb.

15. Prepositions govern the objective case. Under this rule we may remark, that the prepositions *to* and *for* are often understood, chiefly before the pronouns, as "give *me* the book," for *to me*, &c. The preposition is often separated from the relative which it governs; as "whom will you give it to?" for "to whom will you give it?" Some writers separate the preposition from the noun or pronoun which it governs, in order to connect different prepositions with the same word; but this kind of construction is always inelegant, and should generally be avoided. Different relations, and different senses, must be expressed by different prepositions, though in conjunction with the same verb or adjective. Thus we say, "to converse *with* a person, *upon* a subject, *in* a house, &c." When prepositions are subjoined to nouns, they are generally the same that are subjoined to the verbs from which the nouns are derived. Many writers, as Dr. Priestley has observed, affect to subjoin to any word the preposition with which it is compounded, or the idea of which it implies, in order to point out the relation of the words, in a more distinct and definite manner, and to avoid the more indeterminate propositions *of* and *to*: but general practice, and the idiom of the English tongue, seem to oppose the innovation. Thus many writers say, "averse *from* a thing;" but others use "averse *to* it," which is more truly English: "Averse *to* any advice," Swift. "The words *averse* and *aversion*," says Dr. Campbell, "are more properly construed with *to* than with *from*. The examples in favour of the latter preposition are beyond comparison outnumbered by those in favour of the former. The argument from etymology is here of no value, being taken from the use of another language. If, by the same rule, we were to regulate all nouns and verbs of Latin original, our present syntax would be overturned. It is more conformable to English analogy with *to*; the words *dislike* and *hatred*, nearly synonimous, are thus construed."

16. Conjunctions connect the same moods and tenses of verbs,

verbs, and cases of nouns and pronouns, as "Candour is *to be approved and practised.*"

17. Some conjunctions require the indicative, some the subjunctive mood, after them. Those that are of a positive and absolute nature belong to the former class; *e. g.* "*As* virtue *advances, so* vice *recedes.*" When something contingent or doubtful is implied, the subjunctive ought to be used, as "*If I were* to write, he would not regard it." See Subjunctive.

18. When the qualities of different things are compared, the latter noun or pronoun is not governed by the conjunction *than* or *as*, but agrees with the verb, or is governed by the verb or the preposition, expressed or understood; as "Thou art wiser than I," that is, "than I am."

19. For the purpose of avoiding disagreeable repetitions, and of expressing our ideas in few words, an ellipsis, or omission of some words, is frequently admitted; *e. g.* instead of saying "He was a learned man, he was a wise man, and he was a good man," we say, availing ourselves of the ellipsis, "He was a learned, wise, and good man."

20. All the parts of a sentence should correspond to each other; so that a regular and dependent construction may, throughout, be carefully preserved. The following sentence is inaccurate; "He was more beloved, but not so much admired, as Cinthio," it should be, "He was more beloved than Cinthio, but not so much admired."

21. The regimen of verbs is frequently laid on different kinds of relations, according to custom or usage; which yet does not change the specific relation of each case, but only shews, that custom has made choice of this or that, according to fancy. Thus the Latins say, *juvare aliquem*, and *opitulari alicui, to help one.* So the French say, *servir quelqu'un*, and *servir à quelqu'un, to serve one.* Thus the English say, *fight one*, or *fight with one.* And thus, in Spanish, most of the verbs active govern indifferently either a dative or an accusative. Sometimes, also, the verb admits of several regimens; as *præstare aliquem*, or *alicui; eripere morti aliquem*, or *aliquem à morte.*

Indeed, the different regimen sometimes makes an alteration in the sense; in which, particular regard is to be had to the usage of the language. Thus, the Latin *cavere alicui* signifies *to watch*, or *be careful of the preservation of any one; cavere aliquem* signifies *to beware of him.*

There is one very common fault in regimen, which our accurate writers should be careful to avoid; *viz.* the using of two verbs that require different cases together, as only governing one case; as in this example; after *embracing and giving his blessing to his son;* where *embracing* requiring an accusative, and *giving* a dative case, the regimen or construction of the first verb with the noun is irregular; *embrace to a son.*

The same may be observed in nouns; as, *I conjured him by the memory and the friendship he bore my father;* where *memory* does not agree with *he bore.*

For an ample illustration of these rules by appropriate examples, and also of the exceptions which pertain to each respectively, we refer to Mr. Murray's English Grammar, vol. i. ch. 12. See Concord and Syntax.

Regimen, or *Construction, State of, Status regiminis*, a phrase used by Hebrew grammarians in contradistinction to the *absolute state*, or *status absolutus.* A noun in *statu absoluto* is that which does not govern either a genitive or any oblique case; and it is said to be *in regimine* or *in constructione*, when it does govern such case. Nouns of the former kind seldom undergo any change in the letters that form them, as מלכים צדקים, just kings, whereas the latter either lose one of their letters, or undergo a change of one into another; but these latter admit of excepted cases; *e. gr.* singular masculine nouns undergo no change *in regimine* מלך ארץ, king of the land, and plurals throw off the final letter, as מלכי ארץ, kings of the earth, for מלכים ארץ. This is also the case with participles, as פעל און, working iniquity, and פעלי און, workers of iniquity. Singular feminine nouns ending in ה change the ה *in regimine* into ת, as תורת יהוה, the law of the Lord; others, and especially plural nouns, undergo no change מלכת שמים, the kingdom of heaven. We shall here observe, that the change which takes place on account of the state of regimen is made in the governing noun, and not in that which is governed, contrary to the practice in other languages. For other particulars referring to regimen in Hebrew, as well as in Latin, Greek, and other learned languages, we refer to the article Syntax.

REGIMENT, derived from the Fr. *regir*, of *regere*, to govern, or from the Fr. *regime*, denoting system or administration, in *War*, a body consisting of several troops of horse, or companies of foot, commanded by a colonel, lieutenant-colonel, and major; or, as sir James Turner defines it, a certain number of companies joined in one body, under one head. A regiment of cavalry consists of one or more squadrons; and a regiment of infantry of one or more battalions.

The number of men in a regiment is as undetermined as that of the men in a troop, or company; in a squadron or battalion.

A battalion in each regiment of foot is divided into companies, but the number of companies is various; though, in England, our regiments are generally ten companies; two of which are called the flanks; one on the right, consisting of grenadiers, and another on the left, formed of light troops. The squadrons in cavalry, or in regiments of horse, are divided, sometimes into six, and sometimes into nine troops. Each regiment has a chaplain, quarter-master, adjutant, and surgeon. It has been suggested, that every regiment of foot should consist of 2400 men, making three battalions of 800 each.

Some German regiments consist of 2000 foot; and the regiment of Picardy in France consisted of 120 companies, or 6000 men.

The French have distinguished between the commanding officer of a regiment of cavalry, and the commanding officer of a regiment of infantry; the former having been called "maître de camp," and the latter "colonel," as with us. According to the present establishment of the French army, the term "regiment" is confined to the cavalry and artillery, and the name of half brigade is given to the infantry, so that "chêf de brigade," chief of brigade, corresponds with our colonel of a regiment of infantry. In the French cavalry the term colonel is still retained.

Some observe, that there were no regiments of horse before the year 1637. Till then the troops were loose and independent of each other, and not incorporated into a body or regiment.

Regiments, it is said, were first formed in France, under the reign of Charles IX. though F. Daniel refers them to the time of Henry II. and in England to the year 1660. Grose observes, that we may, without being very much mistaken, place the introduction of regiments and colonels about the reign of king Henry VIII.

We shall here annex a brief account of some of the principal regiments of the old corps. The first and second regiments of life-guards claim priority of notice. The life-guards

guards succeeded that body under the same denomination which was raised by Charles II., soon after the restoration, the privates of whom were taken from the cavalier gentlemen, who had adopted the profession of arms, and followed the fortunes of his father during the civil wars. As they were for the most part men of family, they possessed certain privileges, similar to those of the houshold troops in France, after whom they were modelled; and these privileges were continued long after the time when they ceased to be composed of the same class of men. It was, therefore, found necessary to reduce the privates, and to form a new corps, composed almost entirely of recruits under the old officers, and to place them nearly on the same footing with the rest of the cavalry; reserving for them, however, the advantages arising out of a higher pay, and an exemption from stoppages on the part of the privates, whose clothing is furnished by government. The life-guards claim the privilege, that their officers are not liable to be tried by any court-martial, unless the members are composed of their own regiment, or of officers of the other houshold troops. The first regiment of life-guards, consisting of very fine men, about 6 feet high at an average, was formed in 1788. The uniform is scarlet, faced with blue, and gold lace. The commissioned officers are a colonel, one lieutenant-colonel, one supernumerary lieutenant-colonel, two majors, five captains, six lieutenants, one adjutant and lieutenant, five cornets, one surgeon, and one veterinary surgeon. The non-commissioned officers consist of quarter-masters and corporals. The privates are about 260 in number. Their quarters are permanent at Knightsbridge barracks. The second regiment is on the same footing with the first, and of the same establishment. The average height of the men is 5 feet $11\frac{3}{4}$ inches; the horses are from 16 to 18 hands high, of a black colour, with long tails. In this regiment, as well as the other, there are five troops; each troop consisting of one captain, one lieutenant, one cornet, one quarter-master, three corporals, 49 privates, including a farrier, and one trumpeter. Each regiment has one kettle drummer. The officers usually ride bay-horses; the kettle drummers and trumpeters, grey. There are two "gold-sticks," one appertaining to each regiment: their duty is to attend alternately every month on his majesty. See *Life*-Guards.

A body of foot-guards was not regularly organized on the present plan till after the restoration. The regiment of general Monk, created duke of Albemarle, was, in compliment to him, retained on the establishment, when most of the other troops were disbanded. This regiment had been raised about ten years before the period alluded to, at Coldstream, in Scotland; and from this circumstance it assumed the name, which it has borne ever since. The year 1660 may thus be considered as the era of the formation of the foot-guards; and though other regiments were added, the Coldstream had the priority. The guards possess many peculiar honours and privileges: they have precedency of all others; their officers possess a higher rank in the army; and without expence to themselves, when on guard at St. James, they have a plentiful table kept for them by the public, and voted annually in the extraordinaries of the army. The king's person, the royal family, the Tower, and, in times of danger, the bank of England, are in a particular manner under their protection. Their uniforms are royal, with blue facings, and their pay superior to that of the marching regiments. See *Foot*-Guards.

The corps, denominated the royal regiment of horse-guards, blue, commonly called Oxford blues, derives its appellation from the noble family of Oxford, who was its first colonel in 1661. This regiment has distinguished itself on a variety of occasions. The following circumstances are peculiar to this corps. It is the only regiment, denominated "horse," at present on the British establishment. The promotions, that of colonel excepted, are restricted to the regiment. The quarter-masters' commissions are signed by the king, so that they are properly termed commission-officers; whereas in all the other cavalry, or dragoon regiments, quarter-masters are only warrant-officers. The average height of the men is 5 feet $10\frac{1}{2}$ inches. The uniform of the officers is blue, faced with scarlet, gold lace, and buff lining; of the privates, blue, with plain red lappets, very broad buff cross-belts, and gloves of the same colour. The troopers' horses are black, with long tails. The corps consists of nine troops; and to each troop belong four commissioned officers, five non-commissioned officers, and 54 private men: there are, besides, the colonel, one lieutenant-colonel, one major, an adjutant, a regimental surgeon and assistant, and a veterinary surgeon. See *Horse*-Guards.

The establishment of a royal regiment of artillery took place early in the last century; the first commission of colonel having been issued, as it is said, in the first year of the reign of George II. In a short time, the number of companies was augmented from four to eight. The uniform was blue, turned up with red; and waistcoats and breeches of the colour of the facings were then worn by the officers. The artillery take the right of foot on all parades, and likewise of dragoons, when dismounted. Each battalion consists of one colonel commandant, one ditto en-second, one first lieutenant-colonel, two second lieutenant-colonels, one major, ten captains, ten captain-lieutenants, thirty lieutenants, one adjutant, one quarter-master, one surgeon, and one assistant surgeon. The establishment of each company is 120 rank and file. The standard height of the men is 5 feet 9 inches, and upwards. The uniform of the officers is blue, faced with scarlet, gold epaulets, no lace, white waistcoat and breeches, boots, yellow breastplate on a white buff shoulder-belt. The uniform of the privates is blue, with red cuffs and collar, no facings, yellow lace, and buttons impressed with the ordnance arms. The serjeants wear frogged gold lace. The arms of the officers and serjeants are yellow-hilted swords; of the corporals, bombardiers, and privates, carbine and bayonet. The horse artillery have swords and pistols. The officers rise in a regular gradation by seniority. See Artillery.

The first or royal regiment of foot claims a high degree of antiquity. It is undoubtedly the oldest regiment in the service. It is said to have been the body-guard of the Scottish kings, whence it has derived its name of the royal Scots, and to have been put upon the English establishment in 1633. The first colonel was nominated during the reign of Charles I.; but on the fatal issue of the civil wars to that monarch, this corps seems to have been disbanded. At the restoration of Charles II., this regiment was re-established. It consists of two battalions, both commanded by the same colonel: in every other respect they are considered as separate corps. The uniform of the officers is scarlet, faced with blue, gold lace embroidered; that of the private soldiers red, faced with blue and white lace.

The second, or queen's royal regiment of foot, was raised in the year 1661. The regiment being royal, the facings for the whole are blue; the lace for the privates white, with a blue stripe.

The third regiment of foot, called the "Buffs," was put upon the regular establishment of the army in the year 1665. It was denominated the "Buffs," from being the first whose accoutrements were made of leather prepared from the buffalo, after the manner of shamois. The waistcoats, breeches, and

and facings of the coat, were afterwards directed to be made of a correſponding colour. When other regiments aſſumed this part of their appointment, the third acquired the name of the "Old Buffs." This regiment has the excluſive privilege of marching through the city of London by beat of drum. Its uniform is red, with buff facings; buff waiſtcoats and breeches. The 31ſt regiment, which has the ſame uniform, is commonly called the "Young Buffs."

The fourth, or king's own regiment of foot, was raiſed in the year 1680, by Thomas earl of Plymouth. This regiment was the firſt that joined king William, on his landing at Torbay; on which occaſion his majeſty honoured it with the title of the king's own regiment; and directed it to bear in its colours the lion of England, which ſtill continues the badge of the regiment, and is worn on the breaſtplate, buttons, cap, and pouch. The uniform of the regiment, at the beginning of the laſt century, was red, faced with blue velvet, and large velvet cuffs, richly embroidered with gold. The preſent uniform is red, with plain blue facings, ſilver buttons and epaulet, white waiſtcoat and breeches. On the epaulet, buttons, and breaſt-plate, are the crown and garter, and round the latter "The King's own Infantry." In the centre is the lion of England, and under it the number IV in ſmall Roman figures.

The fifth regiment of foot was raiſed by James II.; but it followed the fortunes of the prince of Orange. When the 4th, 5th, and 6th regiments were firſt raiſed, they were not placed upon the Britiſh eſtabliſhment, but ſent by James II. for the ſervice of the ſtates-general. On the abdication of that monarch, and the ſubſequent election of William, prince of Orange, they were numbered and taken into the line, according to the periods at which they landed from Holland. Thus the 4th, which had originally been raiſed after the 5th, arrived in England before it, and took precedence. The 6th, which had been levied before the 5th, returned at a later period than either, and was conſequently placed according to that date. The 5th regiment has been augmented to two battalions, by drafts from the militia; its uniform goſling green facings. The 24th, 54th, and 69th regiments are alſo faced with light green.

The ſixth regiment of foot derives its origin from the ſeven years' war, in the courſe of which the United Provinces of Holland threw off their ſubjection to Spain. Its regular eſtabliſhment did not take place until the year 1673; but it had previouſly ſerved under the three firſt princes of Orange. This was one of the three regiments intended, on their formation, to ſerve in Holland; and, therefore, it was paid by the Dutch republic. It came over to this country with king William, at the revolution in 1688, and was incorporated in our military eſtabliſhment, being numbered as the 6th in the Britiſh line. Its uniform is deep yellow facings, white lace, with yellow and red ſtripes. The 9th, 10th, 12th, 13th, 15th, 16th, 20th, 25th, 26th, 28th, 29th, 30th, 34th, 35th, 37th, 38th, 44th, 46th, 57th, 62d, and 67th regiments have alſo yellow facings and white lace; and are diſtinguiſhed from each other by the variations of the ſtripes, the tinge of the colour, &c.

The ſeventh regiment of foot, or "Royal Fuſileers," was raiſed, with nine others of infantry, and eight of cavalry, under James II., in the year 1685, three years before his abdication. As a fuſileer regiment, the men wear caps, ſimilar to thoſe of the grenadiers, but ſomewhat ſhorter. In all other reſpects they are dreſſed and appointed as the ſoldiers of other battalions. Three years after this, another regiment was raiſed, under the denomination of "Royal Welſh Fuſileers." This partiality for cap regiments is ſaid to have been cauſed by the celebrity of the Britiſh grenadiers, who were eaſily diſtinguiſhed by their caps. (By a regulation in 1800, all the regiments of the line, as well as the guards, are to wear a kind of caps.) The officers of theſe regiments never carried ſpontoons, as the others did, till the late change, but had fuſils, like the officers of the flank companies throughout the army. The other regiments of fuſileers have ſecond lieutenants, inſtead of enſigns. This regiment is peculiar in having none but firſt lieutenants, under the field-officers and captains. The uniform is royal blue facings, with white lace, and a blue ſtripe. The 8th, 18th, 21ſt, 23d, 42d, and 60th regiments have alſo blue or royal facings, but different lace.

The firſt, or king's regiment of dragoon-guards, was raiſed and entered on the eſtabliſhment on the 6th of June 1685. The eſtabliſhment of this regiment, called, during its ſervices in Germany in the courſe of the ſeven years' war, "Bland's dragoons," from the name of the officer who was then at the head of it, is ten troops, each conſiſting of one captain, one lieutenant, one cornet, one quarter-maſter, four ſerjeants, four corporals, one trumpeter, and ſeventy-one rank and file. The average height of the men is 5 feet 10 inches; of the horſes, 15 hands $1\frac{1}{2}$ inch. The uniform of the officers is ſcarlet and gold lace, blue cuffs and collar; no facings on the ordinary uniform. The uniform of the troopers, red jacket, faced half-lappel, blue, white lace, buttons marked K. D. G. The ſerjeants wear gold lace. The ſecond, or queen's dragoon-guards, is one of the eight cavalry regiments raiſed in 1685, the ſecond year after the acceſſion of king James II. to the throne. Five of theſe remain on the Engliſh eſtabliſhment, and three on the Iriſh: of the former five, three are diſtinguiſhed as "Dragoon-guards," the other two as "Dragoons;" the firſt of which is denominated "the king's own regiment." The uniform of the officers red, faced with black velvet and ſilver lace; and that of the troopers red jacket, black collar and cuffs, royal lace, white buttons, marked Q. D. G. The ſerjeants wear ſilver lace. The third, or prince of Wales's dragoon-guards, is the laſt of the three regiments diſtinguiſhed as dragoon-guards upon the Britiſh eſtabliſhment. The uniform is ſcarlet, faced with white, and yellow buttons. The fourth, or royal Iriſh regiment of dragoon-guards, was raiſed, with ſeven others of the cavalry, in the year 1685, ſoon after James II. aſcended the throne. It was originally called "the Prince of Wales's," or firſt regiment of horſe; and, with the other three of horſe upon the ſame eſtabliſhment, it was, in the year 1788, put upon a new one, and called "Dragoon-guards," numbering on to ſeven; ſo that the fourth of horſe, formerly ſo called, is now the ſeventh dragoon-guards. The uniform is royal, with ſilver lace. The fifth regiment of dragoon-guards, commonly called the "Green Horſe," was originally the ſecond of horſe, and raiſed in England in the reign of king James II., in the month of July 1685. It was at that time put upon the regular Britiſh eſtabliſhment. It went over with king William to Ireland in 1689, and remained more than 100 years upon the Iriſh eſtabliſhment. It is now on the Engliſh eſtabliſhment; and conſiſts of nine troops, of the ſame ſtrength with thoſe of the fourth regiment of dragoon-guards; each troop conſiſting of one quarter-maſter, four ſerjeants, four corporals, one trumpeter, and ſeventy-one privates. The uniform of the regiment is green facings with gold lace for the officers, and yellow for the private men. The height of theſe men is in general from 5 feet 8 inches to 6 feet. The firſt, or royal regiment of dragoons, was raiſed for the ſervice of Charles II. in 1683. Their badge is a horſe-ſhoe, incloſing 1ſt D., encircled with a wreath of laurels; the regiment conſiſts of nine troops, of the uſual number. The colour of the horſes is black. The ſecond,

second, or royal North British dragoons, called the "Scots Greys," were raised in Scotland during the reign of James II. The uniform is red, with gold lace, no facings, but blue collar and cuff. The horses are of an iron-grey colour, except those of the officers and trumpeters, which are of a light grey, approaching to white. The fifth, or royal Irish regiment of dragoons, was raised in or about the year 1688. In consequence of the good behaviour of this regiment at the battle of Hochstet, in August 1704, three additional troops were put upon the establishment, making its strength to consist of nine troops. Again this regiment, assisted by the Scots greys, distinguished itself at the battle of Ramillies in 1706; and both corps were distinguished from other cavalry regiments, by being permitted to wear grenadier caps. The permanency of the nine troops was secured by an order, dated in 1798. At this time there was an insurrection of the rebels in the disaffected parts of Ireland, and this regiment was ordered to resist and suppress it. In order to supply the loss it sustained in several conflicts with the rebels, its officers were instructed to receive eligible recruits. Many were enlisted, who, as the event afterwards proved, were rebel-partisans, who entered into a desperate plot for seizing the garrison at Lehaunstoun and massacring every officer and loyal soldier. The conspirators were seized, and suffered according to their deserts. The regiment, however, had the mortification to find it announced in the public papers, that several privates belonging to the fifth or royal Irish dragoons, had been found guilty by a general court-martial of joining the rebels. In consequence of this the regiment was, on the 10th of April following, disbanded by an order from his majesty, dated April 8th, 1799. See Grose's Mil. Ant. vol. ii. appendix.

REGIMENTAL *Court-martial.* See COURT-*Martial.*

REGIMENTAL *Staff.* See STAFF.

REGIMENTALS, the uniform clothing of the army, consisting of a hat, coat, waistcoat, breeches, shirts, stocks, shoes, stockings, spats, spatterdashes, &c.

REGINA, in *Geography*, a town of Naples, in Calabria Citra; 12 miles N. of Cosenza.

REGINA *Aurarum*, in *Ornithology*, a name given by Nieremberg to a bird called by the Mexicans *cozcacoauhtli*. It has obtained its name from its being able to fly against the strongest winds. It is of the bigness of an eagle, and its whole body is of a blackish purple, variegated with a brownish-yellow and deep black; its wings are variegated with black, yellow, and grey; its legs are red; its claws very strong and sharp; and its beak like that of a parrot; it has some rugose skin on the forehead, and about the beak; and its tail is black above, and grey underneath. It feeds on snakes, rats, and other vermin, but will also eat human dung; it flies very high; it is a native of Mexico, and breeds in spring; its feathers are said to be a remedy for many diseases; but the truth of this account is much to be doubted. Ray.

REGINA, *Salve.* See SALVE.

REGINELLI, NICOLA, in *Biography*, an Italian opera singer, renowned for his knowledge and the purity of his taste. He arrived in London in the autumn of 1746, an old but great singer, whose voice as well as person were in ruin. He first appeared on our stage in a pasticcio, called "Annibale in Capua." This performer was now turned of fifty; his voice a *soprano*, but cracked, and in total decay; his figure tall, raw-boned, and gawky; but there were fine remains of an excellent school in his taste and manner of singing; indeed, he had some refinements in his embellishments and expression, that cannot be described, and which we have not since heard in any other singer. In a *cantabile*, his taste, to those who had places near enough to hear his *rifiorimenti*, was exquisite; but the imperfections of his voice and figure disgusted those at a distance, to whose ears only the worst part of his performance arrived.

REGINO, a celebrated German ecclesiastical writer and chronicler, who flourished in the ninth and tenth centuries. He embraced the monastic life at the Benedictine abbey of Prum, in the diocese of Treves, and by his conduct gained such general respect among the fraternity, that in the year 892 he was made abbot, which office, however, from the jealousy of his rivals, he was obliged to resign in 899. After this he probably retired and spent the remainder of his days in the abbey of St. Maximin at Treves. He died about the year 908. He was author of "A Chronicon," extending from the birth of Christ to the year 907, which is said to be very useful in illustrating the history of his time, and particularly that of the Franks and Germans. This chronicon was published at Frankfort in 1583, with an appendix by another hand, continuing it from the year 907 to 972, and it is to be found in Pistorius's collection, entitled, "Scriptores de Rebus Germanicis." Regino was author likewise of "De Disciplinis Ecclesiasticis et Religione Christiana," in two books, of which the first contains those canons which relate to ecclesiastical persons, and the second, those which regard the laity. This work was undertaken by him about the year 906, at the desire of the archbishop of Treves, for the special benefit of his diocese. It was first published, with an appendix, by Joachim Hildebrand, at Helmstadt, in 1659, from a manuscript of Flacius Illyricus; and afterwards by M. Baluse, with additions, and a learned preface and notes, in 1671. Trithemius pronounces Regino to have been the best German writer of his age.

REGINO, in *Geography*, a town of Golo, or the island of Corsica, in the department of Calvi; the canton of which contains 3913 inhabitants.

REGIO ASSENSU, in *Law*, is a writ by which the king gives his royal assent to the election of a bishop.

REGIOMONTANUS, in *Biography*. See MULLER.

REGION, in *Anatomy*, denotes a division of the human body. Some anatomists have divided the body into three regions, or venters.

The upper region is that of the head, reaching as low as the first vertebra, and comprehending the animal organs, the brain, &c. See HEAD, &c.

The middle region is that of the thorax or breast, which Hippocrates calls the upper venter, and which reaches from the clavicles to the diaphragm: in this are contained the vital parts, as the heart, lungs, &c. See HEART, LUNGS, &c.

The third, or lower region, is the abdomen or belly, &c. containing the natural parts, destined for digestion, purgation, and generation. See ABDOMEN.

REGION, *epicolic*, *epigastric*, and *umbilical*. See the adjectives.

REGION, *Regio*, in *Geography*, a country, or particular division of the earth; or a tract of land inhabited by people of the same nation.

The modern astrologers divide the moon into several regions, or provinces, to each of which they give its proper name. See MOON.

REGION, in *Physiology*. Authors divide the atmosphere into three stages, called the *upper*, *middle*, and *lower* regions. See ATMOSPHERE.

The lowest region is that in which we breathe, and is bounded by the reflexion of the sun's rays, that is, by the height to which they rebound from the earth.

The middle region is that in which the clouds reside, where meteors are formed, &c. extending from the extremity of the loweft to the tops of the higheft mountains.

The upper region commences from the tops of the mountains, and reaches to the utmoft limits of the atmofphere. In this reigns a perpetual, equable calmnefs, clearnefs, and ferenity.

Region, *Elementary*. See Elementary.

Region, *Etherial*, is ufed for the whole extent of the univerfe, including the orb of the fixed ftars, &c.

Regions *of the Sea*. As fome naturalifts, in their defcriptions of the fubterraneous parts of the globe, diftinguifh the earth into three regions of different depths, in which different temperatures are obferved; fo in defcribing the fea, they allow it two regions; the one extending from the furface of the water, down fo low as the rays of the fun can pierce, and extend their influence; and the other, from the loweft bounds of that to the bottom. It is eafy to fee that thefe regions rather regard quality than fpace, and that their boundaries are far from being regular, or equal in all places, and at all times. The places expofed to the hotteft funfhine will have the largeft upper region; thofe where the fun has leaft power will have the fmalleft; and the fame part of the fea will have its upper region more or lefs deep, according to the feafon of the year. This upper region of the fea is always more or lefs hot; the lower region, except in fome few particular places, is every where cold; and the water, where the upper region is large, is always remarkably ftill and quiet in the lower. Boyle of Cofmical Qualities.

Region, *Subterranean*. The earth is not only divided on its furface into regions and countries, but philofophers, who have had occafion to difcourfe of its inner parts, have alfo divided them into three diftinct regions, according to their different depths from the furface. The temperature of the fubterranean parts of the globe is diftinguifhed according to the divifion of thefe regions, but is not fo regular and precife as fome have fuppofed. The firft region of the earth is very variable, both as to bounds and temperature. The fecond region feems for the moft part cold, in comparifon of the other two; but in feveral places, which, by reafon of their diftance from the furface of the earth, it would be natural to call the middle region, the temperature of the air is very different at the fame feafons of the year, which fhews that it depends on fomething more than bare depth from the furface. The third region of the earth is univerfally obferved to be warm, but by no means regularly or uniformly: the fame depth in fome places, giving only a moderate warmth, while in others it gives a very confiderable heat.

Borrichius tells us of a certain abbé, fond of chemiftry, and particularly curious in the matter of long digeftions by regular heat, who found a way of making a furnace perpetually warm, by piercing the earth to a certain depth, and ufing the heat of this third region of it. His method, we are told, was to bore a hole with a pike twenty feet deep, and pour into it ten or twelve pounds of quickfilver; this made its way into the ftrata, and through them in a body into the chambers of heat in this third region, where the heat, having a vent upwards, made by this opening, never failed to afcend in a perpetual and regular ftream, and gave that regular and digefting heat that no artificial fire could equal. But this is an alchemical ftory. Boyle of Cofmical Qualities. Borrich. de Ortu Chem.

Region, in ancient Rome, a part or divifion of the city. Romulus divided his little city into three tribes, and Servius Tullius added a fourth; which divifion continued till Auguftus's time, who firft divided the city into fourteen regions, over each of which he fettled two furveyors, called *curatores viarum*, who were made annually, and took their divifions by lot. Thefe fourteen regions contained 424 ftreets, 31 of which were called great or royal ftreets, which begun at the gilt pillar that ftood at the entry into the open place in the middle of the city.

The extent of thefe divifions varied greatly, fome being from 12,000 or 13,000 to 33,000 feet and upwards in circumference. Authors, however, are not agreed as to the exact limits of each.

According to Kennet, who formed his divifion on the authority of the accurate Panvinius, the different regions were as follow: The *firft* region, called "Porta Capena," contained 9 ftreets, 3 luci, or confecrated groves, 4 temples, 6 ædes, or facred buildings, 6 public baths, 4 arches, 14 granaries, 12 mills for grinding corn, and 121 domi, or great houfes. The whole compafs of this region, or ward, was 13,223 feet. The *fecond* region, denominated "Cœlimontium," included 12 ftreets, 2 luci, 5 temples, the public baths of the city, 80 private baths, the great fhambles, 23 granaries, 23 mills, and 133 great houfes. Its compafs was 13,200 feet. The *third* region, or Ifis and Serapis, contained 8 ftreets, 2 temples, the amphitheatre of Vefpafian, the baths of Titus, Trajan, and Philip, 19, or, as fome fay, 29 granaries, 23 mills, 160 great houfes. Its compafs was 12,450 feet. The *fourth* region, Via Sacra, or Templum Pacis, comprehended 8 ftreets, 10 temples, the coloffus of the fun, 120 feet high, the arches of Titus, Severus, and Conftantine, 75 private baths, 18 granaries, 24 mills, and 138 great houfes. Its compafs, according to fome, was only 8000, but, according to others, 14,000 feet. The *fifth* region, or Efquilina, included 15 ftreets, 8 luci, 6 temples, 5 ædes, 75 public baths, 18 granaries, 22 mills, and 180 great houfes. Its compafs was 15,950 feet. The *fixth* region, Acta Semita, contained 12 or 13 ftreets, 15 temples, 2 porticos, 2 circi, 2 fora, 75 private baths, 19 granaries, 23 mills, 155 great houfes. Its compafs was 15,600 feet. The *feventh* region, Via lata, included 40 ftreets, 4 temples, 75 private baths, 3 arches, 17 mills, 25 granaries, and 120 great houfes. Its compafs was 23,700 feet. The *eighth* region, Forum Romanum, included 12 ftreets, 21 temples, 66 private baths, 10 ædes, 9 porticos, 4 arches, 7 fora, 4 curiæ, 7 bafilicæ, 6 columns, 18 granaries, 30 mills, and 150 great houfes. Its compafs was 14,876 feet. The *ninth* region, Circus Flamininus, comprehended 20 ftreets, 8 temples, 20 ædes, 12 porticos, 2 circi, 4 theatres, 3 bafilicæ, 2 curiæ, 5 baths, 2 arches, 2 columns, 32 mills, 32 granaries, and 189 great houfes. Its compafs was 30,560 feet. The *tenth* region, Palatium, contained 7 ftreets, 10 temples, 9 ædes, 1 theatre, 4 curiæ, 15 private baths, 12 mills, 16 granaries, and 109 great houfes. Its compafs was 11,600 feet. The *eleventh* region, Circus Maximus, included 8 ftreets, 22 ædes, 15 private baths, 16 granaries, 12 mills, and 189 great houfes. Its compafs was 11,600 feet. The *twelfth* region, Pifcina Publica, contained 12 ftreets, 2 ædes, 68 private baths, 28 granaries, 25 mills, and 128 great houfes. Its compafs was 12,000 feet. The *thirteenth* region, or Aventinus, included 17 ftreets, 6 luci, 6 temples, 74 private baths, 36 granaries, 30 mills, and 155 great houfes. Its compafs was 16,300 feet. The *fourteenth* region, Tranftiberina, contained 23 ftreets, 6 ædes, 136 private baths, 20 granaries, 32 mills, and 150 great houfes. Its compafs was 33,409 feet.

REGIONARY, Regionarius, in *Ecclefiaftical Hiftory*, a title given, from the fifth century, to perfons who had the charge and adminiftration of the church affairs within a certain diftrict or region.

At Rome there were anciently feven regionary deacons, who

who prefided over a kind of hofpitals, and looked to the diftribution of alms.

There were alfo regionary fubdeacons, and regionary notaries, as alfo regionary bifhops, &c.

A regionary bifhop was properly a miffionary invefted with an epifcopal character, but without being attached to any particular fee, that he might be at liberty to go to preach, and perform other functions of his miniftry, whitherfoever the Spirit of God and the wants of the people fhould call him.

REGIS, Peter-Sylvan, in *Biography*, a celebrated French philofopher, was born at Salvetat de Blanquefort, in the Agenois, in the year 1632. After having been inftructed in claffical learning and the belles lettres, by the Jefuits, at Cahors, he entered himfelf a ftudent of divinity at the univerfity of that city, intending to qualify himfelf for the clerical profeffion. This, however, he abandoned, in order to devote himfelf to the ftudy of the Cartefian philofophy, which at that time was taught with great fuccefs by Rohault. With this view he went to Touloufe in 1605, and read a courfe of lectures upon the principles of Defcartes, and was attended by perfons of all ranks and characters, who inlifted themfelves in the number of his difciples. Among thefe were to be found the magiftrates, clergy, and even the women of Touloufe, who affected to be the zealous converts to the new philofophy, in oppofition to the old. To exprefs their gratitude to the man who had been the inftrument of diffufing this light over their city, the inhabitants granted him a penfion; a circumftance which, it has been obferved, correfponded more with the fpirit and ufages of ancient Greece, than of modern times. In 1680 he came to Paris, confidering that as the moft proper fcene for the exhibition of his talents. Here he was extremely popular, and the friends to the Ariftotelian fyftem began to be alarmed at his fuccefs, and complained againft him to the archbifhop of Paris, who prohibited him from continuing his lectures, and they were accordingly fufpended. But after a fhort time, the prelate withdrew his interdict, and Regis devoted the remainder of his life to the propagation of the Cartefian philofophy, as well by his writings as his lectures. In 1699 he was admitted a member of the Academy of Sciences, but his infirmities prevented him from attending its meetings. He died in the year 1707, at the age of 75, highly efteemed by perfons of the firft diftinction for talents and rank. He was author of a great number of works, of which the following may be mentioned: "A Syftem of Philofophy, containing Logic, Metaphyfics, and Morals;" "An Anfwer to the Book of M. Huet, entitled 'Cenfura Philofophiæ Cartefianæ,'" which is mentioned by Bayle as a model for every writer on the fame fide of the queftion; "An Anfwer to the Critical Reflections of Du Hamel on the Syftem of Philofophy."

Regis, in *Geography*, a town of Saxony, in the bifhopric of Nuremburg; 14 miles S. of Leipfic.

Regis, *St.*, a village of Upper Canada, on the St. Lawrence, half a mile N. from the N. line of the United States. It is feated on a beautiful elevated plain, in the angle between the mouth of St. Regis river and the St. Lawrence. It confifts of about 80 houfes of hewn logs, inhabited by about 100 Indian families, of the Caghnowaya tribe, who have lived here more than half a century. They are peaceable, honeft, and induftrious. Their diverfions are footraces, playing at ball, and dancing. They are Roman Catholics, and have a handfome ftone church, with a fpire, and generally a minifter. Thefe Indians have 30,000 acres of land referved to them S. of the village. They keep a great number of horfes and cattle, and raife plenty of corn on the fertile iflands in St. Lawrence. From St. Regis there is a good road to Plattfburg, on Champlain; the diftance being 72 miles.—Alfo, a river of Canada, which rifes from lakes near Racket river, and enters the St. Lawrence at the village above-mentioned.

Regis *Pondus*. See Pondus.

Regis *Villa*. See Villa.

REGISTAN, or *Sandy Defert of Agimere*, in *Geography*, a fandy defert, forming the weftern boundary of Hindooftan, between the country of Agimere and the Indus. The northern extreme of this defert bounds the dominions of the Seiks on the fouth.

REGISTER, Registrum, a public book ferving to enter and record memoirs, acts, and minutes, to be had recourfe to occafionally, for the juftifying of matters of fact.

Menage derives the word, by corruption, from *regeftum*, a book containing extracts of feveral books, &c. collected together: "Dicitur regeftum quafi iterum geftum." Others derive it from the old French *gifter*, *to lie down in a bed*, &c.

The law of Scotland is rendered very eafy and regular, by means of the great number of regifters, for recording the conveyances of lands, &c. of private perfons. Of thefe there are two kinds: the one general, fixed at Edinburgh, under the direction of the lord regifter, who, before the Union, was the fifth officer of the ftate, and, befides the regiftry, was clerk of the parliament, treafury, exchequer, and feffion.

The other is particularly kept in the feveral fhires, ftewarties, and regalities. The clerks of it are obliged to tranfmit the regifters of their refpective courts to the general regifter; and the notaries their protocols: and here they are fo difpofed, that, on demand, the lieges can have a view of any writs which the law requires to be regiftered, or which parties, for their fecurity, have thought fit to record.

The regifters were firft fet on foot by act of parliament, under king James VI., to the unfpeakable advantage of the fubject.

No man can have a right to any eftate, but it muft be regiftered within forty days of his becoming feifed of it, otherwife it is null; and by this means all fecret conveyances are cut off.

By a law in 1704, it was enacted, that a memorial of all deeds and conveyances, and of all wills and devifes in writing, by which any honours, manors, &c. in the Weft Riding of Yorkfhire, might be any way affected in law or equity, may, at the election of the party or parties concerned, be regiftered: and that, after fuch regifter, every fubfequent deed or conveyance of the faid honours, manors, &c. fo regiftered, or any part of it, fhall be adjudged fraudulent and void, unlefs a memorial of it fhall be alfo regiftered: and the like of wills, &c. But this act did not extend to copyhold eftates, nor to leafes at rack-rent, nor to any leafe not exceeding twenty-one years.

In the year 1708, a fimilar ftatute was paffed for the regiftering of deeds, conveyances, wills, devifes, mortgages, &c. in the Eaft Riding of Yorkfhire: and all the provifions and claufes in this act were hereby extended to the honours, manors, lands, and tenements, in the Weft Riding of the fame county.

In 1709, a law was made for the public regiftering of deeds, conveyances, wills, &c. in the county of Middlefex; which may be done for the fee of one fhilling: and every deed or conveyance, which fhall hereafter be executed, fhall be adjudged fraudulent and void, againft any fubfequent purchafer or mortgagee for valuable confideration, unlefs fuch memorial of it be regiftered according to the direction of of this act, before the registering of the memorial of the deed or conveyance, under which such subsequent purchaser or mortgagee shall claim; and the like as to memorials of wills not registered.

In 1735, a similar register of mortgages, &c. was legally enacted for the North Riding of the county of York; whence York and Middlesex are register counties. (2 & 3 Ann. cap. 4. 6 Ann. cap. 35. 7 Ann. cap. 20. 8 Geo. II. cap. 6.) These statutes do not extend to copyhold estates, leases at a rack-rent, or to any leases not exceeding 21 years, where the possession goes with the lease; nor to any chambers in the inns of court.

Many have wished that the same regulation was extended to all the counties of England and Wales; but judge Blackstone observes, that, however plausible these provisions may appear in theory, it hath been doubted, by very competent judges, whether more disputes have not arisen in those counties, by the inattention and omission of parties, than prevented by the use of registers.

Register, more correctly *Registrer*, *Registrarius*, is also used for the clerk, or keeper of a register, or registry.

Of these we have several, denominated from the registers they keep; as register of the high court of delegates, registers of the arches court of Canterbury, register of the court of admiralty, register of the prerogative court, registers of the province of Canterbury, register of the archdeaconry of Middlesex, &c. register of the faculty office, and register of the garter, who is always dean of Windsor, and deputy registers.

There are also, in the court of chancery, the principal register, the lord chancellor's registers, the registers of the master of the rolls, entering registers, and register of the affidavits.

The appellation of register or registrarius is also given to a notary. See Notary, and Notary, *Public*.

Register, *City*. See Town-*Clerk*.

Register of a parish church, is a book in which the yearly baptisms, marriages, and burials, of each parish, are orderly registered. See Marriage.

This practice was laudably instituted by that great but unfortunate person Thomas Cromwell, earl of Essex, anno 1538, while he was vicar-general to king Henry VIII.; and it was continued in the reigns of king Edward VI. and of queen Elizabeth.

These parish registers are to be kept in a coffer, provided by the churchwardens, with three locks and keys, one of which is to remain with the minister, and the other two with the churchwardens severally, so that neither the minister without the two churchwardens, nor the churchwardens without the minister, shall at any time take that book out of the said coffer. These parish registers are to be subscribed by the minister and churchwardens; and the names of the persons shall be transmitted yearly to the bishop; and it has been enforced by canon 70, and by statute, &c.

By 26 Geo. II. c. 33. to make a false entry in a marriage register, to alter it when made, to forge or counterfeit such entry or a marriage licence, or aid and abet such forgery, to utter the same as true knowing it to be counterfeit, or to destroy or procure the destruction of any register, in order to vacate any marriage, or subject any person to the penalties of this act; all these offences, knowingly and wilfully committed, subject the party to the guilt of felony, without benefit of clergy.

By the 30 C. II. c. 5. for burying in woollen, it is enacted, that the minister of every parish shall keep a register in a book to be provided at the charge of the parish, and make a true entry of all burials within his parish, and of all affidavits of persons being buried in woollen brought unto him according to the said act; and where no such affidavit shall be brought to him within the time therein limited, he shall enter a memorial thereof in the said registry, against the name of the party interred, and of the time when he notified the same to the churchwardens or overseers of the poor according to the said act.

An approved register of births, consisting of certificates signed by two persons who were present at the said births, and entered in a book signed by the register or secretary, is kept with great accuracy, and authenticated by a committee, for the benefit of Protestant dissenters and others. This book is deposited and carefully preserved at Dr. Williams's library, Red-cross Street, Cripplegate, to which any person may have free access at the stated hours, under the direction of the secretary of the said library, whose attention to his office entitles him to public respect.

Register is also a title of a book, containing the forms of most of the writs, original and judicial, used in common law. This is called the *register of writs*, or *registrum omnium brevium*. This register, Coke on Littleton observes, is one of the most ancient books of the common law. And judge Blackstone observes concerning it, that it is the most ancient and highly venerable collection of legal forms, upon which Fitzherbert's Natura Brevium is a comment, and in which every man, who is injured, will be sure to find a method of relief, exactly adapted to his own case, described in the compass of a few lines, and yet without the omission of any material circumstance.

Register, in *Antiquity*, a book or table at Athens, belonging to each particular φρατρία, or ward, in which all fathers were obliged to enrol their sons, making oath, at the same time, that every son, so registered, was either born to them in lawful wedlock, or lawfully adopted. The adopted sons were registered in the festival Thargelia; the natural, upon the third day of the festival Apaturia.

At what age children were thus registered is not agreed. Some are of opinion, that at every return of the Apaturia it was customary to register all the children that had been born that year. Others affirm, that they were commonly three or four years old before they were registered.

There were two other seasons when young Athenians were enrolled in a public register: one, when they arrived at the age of eighteen years, and were admitted into the number of the ἔφηβοι, and was performed on the third day of the festival Apaturia; and the other, before the festival Panathenæa, when those who were twenty years old were entered in a register, called ληξιαρχικὸν γραμματεῖον, in which the names of all persons of that borough, who were of age to succeed in the λῆξις, or inheritance of their fathers, were entered. This was termed *to be registered among the men*: and the persons, thus enrolled, became their own masters, and free from the government of their guardians. Potter's Arch. Græc. vol. i. p. 48.

Registers *of Estates*, the accounts of particular things which belong to them, as those of rentals, valuations of fields, names, admeasurements, different portions of land, cottages, and other buildings distinct from the farms, and any other separate parts. In these registers the valuations are to be inserted in columns, as they arise from surveys or other ways, and afford the means of fixing the real values in re-letting the lands or for other purposes.

Also, a general register of the *timber trees* which are growing on the several divisions of the estates, should always be kept; in which the number contained in each separate wood, grove, hedge-row, or any other part, must be entered,

tered, with their kinds, and the admeafurement of each, for the ufe of the proprietor and wood managers.

A great many other forts of particulars regarding the eftates may likewife be ufefully and conveniently put down in thefe regifters.

Register *of Seamen.* See Manning *the Fleet.*

Register *Ships*, or *Ships of Regifter*, in *Commerce*, were veffels to which the king of Spain, or the council of the Indies, granted permiffion to go and traffic in the ports of Spanifh America.

They were thus called, becaufe the fhips were to be regiftered before they fet fail from Cadiz, which was the place where they ufually loaded for Bueuos Ayres.

Thefe veffels, by the tenor of the cedula or permit, were not to exceed three hundred tons; but there fubfifted that good underftanding between the merchants and the council of the Indies, that fhips of five or fix hundred tons frequently paffed unnoted.

Thefe regifter fhips, which were firft introduced in order to furnifh America with a regular and timely fupply, and thus to prevent a contraband trade with the Englifh, French, and Dutch iflands, were fitted out, during the intervals between the ftated feafons, when the galleons and flota failed, by merchants in Seville or Cadiz, upon obtaining a licence from the council of the Indies, for which they paid a very high premium, and were deftined for thofe ports where any extraordinary demand was forefeen or expected. In proportion as experience manifefted the advantages of carrying on trade in this mode, the number of regifter fhips increafed, and at length, in the year 1748, the galleons, after having been employed upwards of two centuries, were finally laid afide. From that period there has been no intercourfe with Chili and Peru, but by fingle fhips difpatched from time to time, as occafion requires, and when the merchants expect a market will open. Thefe fail round Cape Horn, and convey directly to the ports in the South fea the productions and manufactures of Europe, for which the people fettled in thofe countries were formerly obliged to repair to Porto Bello or Panama.

But as all the regifter fhips deftined for the South feas were obliged to take their departure from Cadiz, and were under a neceffity of returning thither, this branch of the American commerce, even in its new and improved form, continued fubject to the reftraints of a fpecies of monopoly, and felt its pernicious effects.

The intercourfe between Spain and her colonies has in later times been much improved and facilitated. In the year 1764, Charles III. appointed packet-boats to be difpatched on the firft day of each month from Corunna to the Havanna or Porto Rico. From thence letters are conveyed in fmaller veffels to Vera Cruz and Porto Bello, and tranfmitted by poft through the kingdom of Tierra Firmé, Granada, Peru, and New Spain. Packet-boats alfo fail with the fame regularity, once in two months, to Rio de la Plata, for the accommodation of the provinces to the eaft of the Andes.

With this new arrangement for facilitating intercourfe a fcheme of extending commerce has been more immediately connected. Each of the packet-boats, which are veffels of fome confiderable burden, is allowed to take in a loading of fuch commodities as are the product of Spain, and moft in demand in the ports whither they are bound. In return for thefe, they may bring home to Corunna an equal quantity of American productions. This regulation may be confidered as the firft relaxation of thofe rigid laws, which confined the trade with the new world to a fingle port, and the firft attempt to admit the reft of the kingdom to fome fhare in it. This meafure of relaxation was foon followed by another more decifive. In the year 1765, Charles III. laid open the trade to the windward iflands, Cuba, Hifpaniola, Porto Rico, Margarita, and Trinidad, to his fubjects in every province of Spain. This ample privilege was foon after extended to Louifiana, and to the provinces of Yucatan and Campeachy. As foon as this general liberty was permitted, it produced the moft beneficial effects: and it has been computed, that fuch a number of fhips was foon employed in the free trade, that the tonnage of them far exceeded that of the galleons and flota, at the moft flourifhing era of their commerce. This arrangement extended its good effects through every province of the kingdom; and by opening a new market for their various productions and manufactures, encouraged and added avidity to the induftry of the farmer and artificer. Spain has alfo permitted a free trade between the colonies themfelves. In the year 1774 Charles III. publifhed an edict, granting to Peru, New Spain, Guatimala, and Granada, the privilege of a free trade with each other. See Robertfon's Hift. of America, vol. iii.

Register, among *Letter Founders*, is one of the inner parts of the mould in which the printing types are caft. Its ufe is to direct the joining of them juftly together again, after opening them to take out the new-caft letter.

Register, in *Printing*, the difpofing of the forms of the prefs, fo as that the lines and pages printed on one fide of the fheet meet exactly againft thofe on the other; which is done by means of two points in the greater or outward tympan.

Register, in *Organ-building*, is another word for a ftop in that inftrument; but is in fact only a lath pierced with holes, correfponding with thofe in the found-board, which by drawing out the ftops opens the holes, and putting them in fhuts them. By thefe fliders each ftop fpeaks or is filent. Regifter is figuratively ufed by muficians in fpeaking of a voice, in which real and falfet notes are not well united. Mr. Braham's *high* notes, for example, are faid to be of a different regifter from the *low*.

Registers, in *Chemiftry*, are holes, or chinks, with ftopples to them, contrived in the fides of furnaces, to regulate the fire; *i. e.* to make the heat immediately more intenfe, or remifs, by opening them to let in the air, or keeping them clofe to exclude it. See Fire-*places* and Furnace.

REGISTRY, Registrum, comprehends the office, books, and rolls, in which the proceedings of chancery, or any fpiritual court, are regiftered or recorded.

REGISTRY *of Shipping*, in *Commerce*. The regiftering of fhips appears to have been firft introduced into this country by the Navigation *Act*, 12 Car. II. c. 18. § 10. By this ftatute, however, foreign fhips only, "Britifh owned," were required to be regiftered. By ftat. 7 & 8 W. III. c. 22. § 17, Britifh or plantation built fhips, Britifh owned, if intended to be employed in the plantation trade, and alfo all "prize fhips," were required to be regiftered; and in confequence of a regulation at the admiralty, fhips for which Mediterranean paffes were wanted, were alfo to be regiftered. The provifions in the acts requiring regiftry are founded upon the wifeft policy, and are not lefs calculated to prevent the commiffion of private fraud upon individuals, than to advance the public policy of the ftate. By ftat. 26 Geo. III. c. 60. (lord Hawkefbury's act), no fhip or veffel foreign built (except fuch as have been condemned as lawful prize in any court of admiralty), nor any fhips or veffels built or rebuilt upon any foreign made keel or bottom, although owned by Britifh fubjects, and navigated according

according to law, ſhall be entitled to the privileges of a Britiſh built ſhip, or of a ſhip owned by Britiſh ſubjects; and all the privileges and advantages allowed ſhall be confined to ſuch ſhips only as are wholly of the built of Great Britain or Ireland, Guernſey, Jerſey, and the Iſle of Man, or ſome of the plantations in Aſia, Africa, or America, now belonging, or which may hereafter belong to his majeſty, except ſuch foreign built veſſels as before the 1ſt of May 1786 did truly and wholly belong to Britiſh ſubjects, navigated according to law, and duly regiſtered, which ſhall continue to enjoy the privileges to which ſuch ſhip or veſſel is by law entitled; nor ſhall this act prevent any ſuch veſſel which may have been begun to be repaired or rebuilt before the 1ſt of May 1786 from being regiſtered, provided it ſhall appear upon oath, to the ſatisfaction of the commiſſioners of the cuſtoms, that ſuch veſſel was ſtranded by the act of Providence, and was at the time of being ſo ſtranded the ſole property of ſome foreigner, or a droit of the admiralty; and if it ſhall appear that ſuch veſſel, from the damage received, was rendered unfit to proceed to ſea without undergoing a thorough repair in this kingdom, and that ſhe was neceſſarily ſold for the benefit of the foreign owners, or under an order or commiſſion from the court of admiralty, and that ſhe was fairly and openly purchaſed by a Britiſh ſubject, and being the ſole and entire property of ſuch Britiſh ſubject, that ſhe had been ſo much repaired, that two-thirds of her at leaſt are of Britiſh built, ſhe may be regiſtered. ſ. 1.

No veſſel ſhall be deemed Britiſh built, or enjoy the privileges belonging to Britiſh built veſſels, which ſhall be rebuilt or repaired in any foreign port, if ſuch repairs ſhall exceed 15*s.* for every ton, unleſs ſuch repairs ſhall be rendered neceſſary by extraordinary damage, and abſolutely neceſſary to enable her to perform the voyage, and to return in ſafety to ſome place or port within his majeſty's dominions; and before ſuch veſſel ſhall be ſo repaired, the maſter ſhall report her ſtate and condition upon oath to the Britiſh conſul or other chief officer at the port where ſuch repairs may be neceſſary, and cauſe the ſame to be ſurveyed by two perſons to be approved of by ſuch conſul or chief Britiſh officer, and ſhall deliver to ſuch conſul or officer, in writing, the particulars of the damage ſuſtained, and verify upon oath the particulars and amount of the repairs, and that the ſame were become neceſſary in conſequence of damage ſuſtained during her voyage, to enable the ſame veſſel to proſecute her intended voyage, and to return to ſome port within his majeſty's dominions, which muſt be certified under the hand and ſeal of the chief conſul or other officer; or if no ſuch conſul, &c. ſhall be there reſident, the ſurvey ſhall be made by two perſons to be approved of by two known Britiſh merchants reſiding at or near ſuch port. And the maſter of ſuch ſhip ſhall produce to ſuch merchants vouchers of the particulars and amount of the repairs, and their certificate ſhall be of the ſame effect as that of the Britiſh conſul or chief officer. And the maſters of veſſels repaired in any foreign port ſhall make oath before the collector and comptroller, or other principal officer of the cuſtoms in the firſt port of arrival (if required ſo to do), deſcribing the nature and amount of ſuch repairs; and if ſuch expence ſhall exceed 15*s.* *per* ton, and the maſter or commander of ſuch ſhip ſhall neglect or refuſe to deliver to ſuch collector or comptroller, or other principal officer of the cuſtoms, the certificate by this act required to be produced, ſuch veſſels ſhall to all intents and purpoſes be deemed foreign built. ſ. 2.

Ships above 15 tons Britiſh owned ſhall be regiſtered in the manner hereinafter mentioned, and the perſons claiming property therein ſhall cauſe the ſame to be regiſtered, and obtain a certificate of ſuch regiſtry from the collector or comptroller of the cuſtoms of Great Britain, or the Iſle of Man, or from the governor, lieutenant-governor, or commander-in-chief and principal officer of the cuſtoms reſident in the iſlands of Guernſey or Jerſey, or in any of the ſaid colonies, plantations, or iſlands reſpectively.

By § 4, no regiſtry is to be made except in the port to which the veſſel belongs.

The port to which any ſhip or veſſel ſhall hereafter be deemed to belong, ſhall be the port from or to which the ſame ſhall uſually trade, or being a new ſhip, ſhall intend ſo to trade, and at or near which the huſband or acting owners uſually reſide.

No American veſſel ſhall be entitled to be regiſtered, or to any of the privileges of a Britiſh built ſhip or veſſel, unleſs ſuch ſhip ſhall have been taken and condemned as lawful prize, or having been ſtranded, ſhall have been built or rebuilt, and regiſtered in the manner before practiſed and allowed. ſ. 7.

No regiſtry ſhall be made or certificate granted until oath be taken and ſubſcribed before the perſons herein before authoriſed to make ſuch regiſtry and grant ſuch certificate, by the owner of ſuch ſhip or veſſel, if the ſame belong to one perſon only; or, in caſe there ſhall be two joint-owners, then by both of them, if both be reſident within 20 miles of the port where ſuch regiſtry required, or by one of ſuch owners, if one or both be reſident at a greater diſtance; or if the number of ſuch owners ſhall exceed two, then by the greater number of them, if the greater number ſhall be reſident within 20 miles of ſuch port, not exceeding three of ſuch owners, or by one of ſuch owners, if all ſhall be reſident at a greater diſtance. ſ. 9 and 10.

In caſe the owners ſhall amount to three or more, and three of ſuch owners ſhall not perſonally attend to take and ſubſcribe the oath directed, then ſuch owner or owners as ſhall attend and take and ſubſcribe the oath, ſhall further make oath that the part-owner or part-owners abſent, is or are not reſident within 20 miles, and hath or have not, to his or their knowledge or belief, wilfully abſented himſelf or themſelves to avoid taking the ſaid oath, or is or are prevented by illneſs. ſ. 11.

By way of identifying the veſſel to which a certificate of regiſtry is alleged to be granted, the ſurveying officer ſhall go on board ſuch ſhip or veſſel as is to be regiſtered, and ſtrictly admeaſure the ſame in the preſence of the maſter, or any other perſon appointed for that purpoſe on the part of the owners, or by the ſaid maſter, and ſhall deliver a true account in writing of all ſuch particulars of the built, deſcription, and admeaſurement of ſuch ſhip or veſſel as are ſpecified in the certificate, to the perſon authoriſed to make ſuch regiſtry; and the ſaid maſter or ſuch perſon as ſhall attend on the part of the owners, is to ſign his name to the certificate of ſuch ſurveying officer, provided ſuch maſter or other perſon ſhall conſent and agree to the ſeveral particulars ſet forth in the ſaid certificate. ſ. 12.

Surveying officers making or granting falſe certificates to forfeit 100*l.*, and be for ever incapable of holding any office under his majeſty. ſ. 13.

The tonnage of any veſſel when afloat is to be aſcertained by the following method, *viz.* drop a plumb line over the ſtern of the ſhip, and meaſure the diſtance between ſuch line and the after part of the ſtern poſt at the load water mark; then meaſure from the top of the ſaid plumb line, in a parallel direction with the water, to a perpendicular point immediately over the load water mark, at the fore part of the main ſtem; ſubtracting the above diſtance from ſuch admeaſure-admeafurement, the remainder will be the fhip's extreme length, from which are to be deducted three inches for every foot of the load draught of water for the rake abaft, and alfo three-fifths of the fhip's breadth for the rake forward; the remainder fhall be efteemed the juft length of the keel to find the tonnage; and the breadth fhall be taken from outfide to outfide of the plank in the broadeft part of the fhip, either above or below the main-wales, exclufive of all manner of fheathing or doubling, that may be wrought upon the fide of the fhip; then multiplying the length of the keel for tonnage by the breadth fo taken, and that product by half the breadth, and dividing by 94, the quotient fhall be deemed the true contents of the tonnage. Nothing in this act to be conftrued to alter the manner of admeafuring the tonnage of any fhip which has heretofore been practifed for the purpofe of afcertaining the light duties, or any other duties or impofts payable according to the tonnage of any veffel. f. 14.

At the time of obtaining the certificate of regiftry, bonds fhall be given to his majefty by the mafter, and fuch of the owners who fhall attend, in the following penalties:

If a decked veffel, or from 15 to 50 tons, 100*l.*; 50 to 100 tons, 300*l.*; 100 to 200 tons, 500*l.*; 200 to 300 tons, 800*l.*; 300 and upwards, 1000*l.*

The condition of every bond given upon regiftry fhall be, that fuch certificate fhall not be fold, lent, or otherwife difpofed of to any perfon or perfons whomfoever, and that the fame fhall be folely ufed for the fervice of the fhip or veffel for which it was granted; and that in cafe fuch veffel fhall be taken by the enemy, burned or broken up, or otherwife prevented from returning to the port to which fhe belongs, the certificate, if preferved, fhall be delivered up within one month after the arrival of the mafter in any port or place in his majefty's dominions, to the collector or comptroller of fome port in Great Britain, or the Ifle of Man, or of the Britifh plantations, or to the governor, lieutenant-governor, or commander-in-chief for the time being, of the iflands of Guernfey or Jerfey; and that if any foreigner, or any perfon or perfons for his ufe and benefit, fhall purchafe, or otherwife become entitled to the whole or any part or fhare of, or any intereft in fuch veffel, and the fame fhall be within the limits of any port in Great Britain, Guernfey, Jerfey, Man, or the Britifh colonies, plantations, iflands, or territories aforefaid, then in fuch cafe the certificate of regiftry fhall, *within feven days after fuch purchafe or transfer of property* in fuch fhip or veffel, be delivered up to the perfon or perfons authorifed by this act to make regiftry and grant certificates thereof at fuch port and place refpectively; and if fuch fhip or veffel fhall be in any foreign port when fuch purchafe or transfer fhall take place, then that the fame fhall be delivered up to the Britifh conful or other chief Britifh officer refident at or neareft to fuch foreign port; or if fuch veffel fhall be at fea, at the time of fuch transfer of intereft and property, then the faid certificate of regiftry fhall be delivered up to the Britifh conful or other chief Britifh officer at the foreign port or place in or at which the mafter or other perfon having or taking the command of fuch fhip or veffel fhall firft arrive after fuch purchafe or transfer of property at fea, immediately after his arrival at fuch foreign port; but if fuch mafter abovementioned in the cafe above-mentioned fhall not arrive at a foreign port, but fhall arrive at fome port of Great Britain, Guernfey, Jerfey, Man, or his majefty's faid colonies, plantations, iflands, or territories, then the faid certificate fhall be delivered up in manner above-mentioned, within 14 days after the arrival of fuch fhip or veffel, or of the perfon who had the command thereof, in any port of Guernfey, Jerfey, Man, or any of his majefty's faid colonies, plantations, iflands, or territories. And if any pafs, called a Mediterranean pafs, fhall have been obtained and procured by any fuch fhip or veffel, then and in fuch cafe the fame fhall be delivered up at the fame time, and in like manner with the certificate of regiftry, to the perfons herein before authorized to receive fuch certificate of regiftry: and fuch certificates fo delivered up, fhall be tranfmitted forthwith to the commiffioners of the cuftoms in England and Scotland refpectively; and fuch Mediterranean paffes fhall alfo be tranfmitted to the admiralty of Great Britain, by the perfon or perfons authorized to receive fuch certificate and paffes, that the fame may be cancelled. f. 15.

In cafe of any alteration of property in the fame port by the fale of any fhare or fhares in any fhip or veffel after regiftering thereof, fuch fale or transfer of property fhall always be acknowledged by indorfement in the certificate of regiftry, before two witneffes, in order to prove that the entire property in fuch fhip is vefted in fome of the fubjects of Great Britain. In cafe any difpute fhould arife concerning the fame, the above indorfement to be figned by the perfon transferring the property in fuch fhip or veffel, or by fome perfon legally authorifed for that purpofe. 7 & 8 W. III. c. 22. f. 21. 34 Geo. III. c. 68. f. 15, and by ftat. 26 Geo. III. c. 60. f. 16.

In addition to the above indorfement there fhall alfo be indorfed on the certificate of regiftry, before two witneffes, the town, place, or parifh, where all perfons to whom the property in any fhip or veffel fhall be transferred fhall refide; or if fuch perfons ufually refide abroad, but in fome Britifh factory, then the name of fuch factory of which fuch perfons are members; or if fuch perfons refide in any foreign town or city, the name of fuch foreign town or city, and alfo the names of the houfe or copartnerfhip in Great Britain or Ireland for or with whom fuch are agents or partners; and the perfon to whom the property of fuch fhip or veffel fhall be fo transferred, or his agent, fhall deliver a copy of fuch indorfement to the perfon authorifed to make the regiftry, who is to caufe an entry to be indorfed on the oath or affidavit upon which the original certificate of regiftry of fuch fhip or veffel was obtained; and alfo to make a memorandum in the book of regifters, and forthwith give notice to the commiffioners of the cuftoms in England or Scotland, under whom they refpectively act.

The certificate of regiftry of fuch veffel fhall be recited in words at length in the bill or inftrument of fale thereof, otherwife fuch bill of fale fhall be utterly void. f. 17.

As often as the mafter or commander of any regiftered veffel fhall be changed, the mafter or owner thereof fhall deliver to the perfon authorifed to make fuch regiftry at the port where fuch change fhall take place, the certificate of regiftry belonging to fuch fhip or veffel, who fhall indorfe and fubfcribe a memorandum of fuch change, and fhall give notice to the proper officer of the port where fuch fhip or veffel was laft regiftered; who fhall likewife make a memorandum of the fame in the regifter book, and give notice to the commiffioners of the cuftoms in England and Scotland. f. 18.

No owner of any fhip or veffel fhall be permitted to give any other name thereto than that by which fhe was firft regiftered. And all owners of regiftered veffels fhall, within one month from the regiftry, paint in white or yellow letters, of a length not lefs than four inches, upon a black ground, on fome confpicuous part of the ftern (provided there fhall be fufficient fpace, but if not, then in letters as large as fuch fpace will admit), the name by which fuch fhip or veffel fhall have been regiftered, and the port to which

which ſhe belongs, and ſo keep and preſerve the ſame. And if ſuch owner, or maſter or commander of ſuch ſhip or veſſel ſhall wilfully alter, eraſe, or conceal, or permit the ſame to be done, unleſs in the caſe of ſquare rigged veſſels in time of war, or ſhall in any written or printed paper deſcribe ſuch ſhip by any other name than that by which ſhe was firſt regiſtered, or ſhall verbally deſcribe ſuch ſhip or veſſel by any other name to any officer of the revenue in the due execution of his duty, ſuch owner or commander thereof ſhall forfeit the ſum of 100*l*. ſ. 19.

By ſtat. 26 Geo. III. c. 60, all perſons who ſhall apply for a certificate of regiſtry in Great Britain, Guernſey, Jerſey, or the Iſle of Man, for any ſhip which ſhall be built, or whoſe building ſhall be completed after the 1ſt of Auguſt 1786, ſhall produce to the perſon authoriſed to grant ſuch certificate a true account under the hand of the builder of the ſame, of the proper denomination, the time when, and the place where ſuch ſhip or veſſel was built, and an exact account of the tonnage, together with the name of the firſt purchaſer; and alſo make oath before the perſon authoriſed to grant ſuch certificate, that the ſhip or veſſel for which ſuch certificate is required is the ſame with that ſo deſcribed by the builder. And every perſon applying for a like certificate in any of his majeſty's colonies, plantations, or territories, ſhall, before ſuch certificate is granted, produce the like account, under the builder's hand, and take the like oath as is required to be produced and taken by perſons applying in Great Britain. ſ. 20, 21.

If any certificate of regiſtry ſhall have been loſt, a regiſter and certificate *de novo*, in the form herein directed, ſhall be granted for ſuch veſſel, according to 15 Geo. II. c. 31; but in all ſuch caſes ſuch ſecurity ſhall be given as is directed in this act, and in lieu of the oath preſcribed by 15 Geo. II. the like oath ſhall be taken and ſubſcribed as hereinbefore directed, by the owner or owners of ſuch ſhips and veſſels as are required to be regiſtered by this act. ſ. 22, 23.

If any ſhip or veſſel ſhall, after regiſtry, be altered, either in form or burthen, or in any manner whatſoever, ſuch ſhip or veſſel ſhall be regiſtered *de novo* as ſoon as ſhe returns to her port, or to any other port in which ſhe may be regiſtered by virtue of this act; on failure whereof ſuch ſhip or veſſel ſhall be conſidered as a foreign veſſel. ſ. 24.

The owners of all ſuch ſhips as ſhall be condemned as lawful prize, ſhall, upon regiſtry thereof, before any certificate of regiſtry ſhall be obtained, produce to the proper officer of the cuſtoms a certificate of the condemnation of ſuch veſſel, and alſo a true account in writing of all the particulars contained in the certificate herein-before ſet forth, to be made and ſubſcribed by one or more ſkilful perſons to be appointed by the court to ſurvey ſuch ſhip or veſſel; and ſhall alſo make oath before the ſaid officer, that ſuch ſhip or veſſel is the ſame ſhip or veſſel mentioned in the certificate. ſ. 25.

No ſhip condemned as prize ſhall be regiſtered in the iſlands of Guernſey, Jerſey, or the Iſle of Man, although belonging to his majeſty's ſubjects reſident in thoſe iſlands; but the ſame ſhall be regiſtered either at Southampton, Weymouth, Exeter, Plymouth, Falmouth, Liverpool, or Whitehaven, by the collector and comptroller at ſuch port reſpectively. 26 G. III. c. 60. ſ. 26.

In all caſes where any ſhip or veſſel taken and condemned in any of his majeſty's colonies, plantations, or iſlands aforeſaid, ſhall be regiſtered, and obtain a certificate, an exact account ſhall be ſubjoined thereto of the ſum for which ſuch ſhip or veſſel ſhall have been ſold, verified upon the oath of the perſon applying for ſuch certificate of regiſtry. ſ. 27.

All certificates, hereafter to be granted in purſuance of this act, ſhall diſtinguiſh whether ſuch ſhips or veſſels be of the built of Great Britain, Guernſey, Jerſey, or the Iſle of Man, or of the colonies, plantations, iſlands, or territories aforeſaid, or of any foreign country; and ſhall, if Britiſh built, be entitled "Certificate of Britiſh plantation regiſtry," and if foreign built, ſhall be entitled "Certificate of foreign ſhip's regiſtry for the European trade, Britiſh property," as the caſe may be. ſ. 28.

No ſhip or veſſel, directed by this act to be regiſtered, ſhall be permitted, after the firſt arrival at the port to which ſhe belongs, at the expiration of the notice by this act directed, to clear outwards for foreign parts, or coaſtwiſe, or to proceed to ſea for the purpoſe of fiſhing on the coaſts, or for any other purpoſe, as a Britiſh ſhip or veſſel, unleſs the owners thereof ſhall have obtained a certificate; and in caſe ſuch ſhip or veſſel depart from ſuch port without being regiſtered, and without having obtained a certificate, every ſuch ſhip or veſſel, with all her guns, furniture, ammunition, tackle, and apparel, ſhall be ſubject to forfeiture. ſ. 32.

If, after the expiration of the before-mentioned notice, any ſhip or veſſel (being ſquare rigged) ſhall be found in any port within 20 leagues by water from the port to which ſhe belongs, or if any veſſel, not ſquare rigged, be found within any port other than that to which ſhe belongs, without having a certificate of regiſtry hereinbefore directed, it ſhall be lawful for the principal officer of ſuch port, and he is hereby required to detain ſuch until the maſter or commander ſhall, if ſuch ſhip or veſſel be under 50 tons, give ſecurity by bond in 50*l*. in manner hereinafter directed; and if the ſame ſhall exceed 50 and not exceed 100 tons, ſhall give ſecurity by bond in 100*l*.; and if the ſame ſhall exceed 100 tons, then until the maſter or commander ſhall with one ſecurity give bond in 200*l*., with condition that ſuch maſter or commander ſhall forthwith repair with her to the port to which ſhe belongs, and there cauſe her to be regiſtered, procure a certificate, and deliver to ſuch officer ſuch certificate within the time limited in the condition of ſuch bond; which time is to be fixed according to the diſtance of the veſſel from the port to which ſhe belongs, and the nature of the voyage in which ſhe may be engaged; and on failure of producing ſuch certificate, ſuch bond ſhall be forfeited; but if the certificate be produced within the time ſo limited, ſuch bond ſhall be void. And in caſe any ſquare rigged veſſel ſhall be found in port, after the expiration of the aforeſaid notice, more than 20 leagues diſtant by water from the port to which ſhe belongs, or that the water at the entrance of the port to which ſhe belongs ſhall be ſo ſhallow as not to admit her entrance, the maſter or commander ſhall, within 48 hours after his arrival at ſuch port, make known his arrival to the collector and comptroller of the cuſtoms, or other principal officer of ſuch port; and ſhall require ſuch collector and comptroller to cauſe his ſhip or veſſel to be ſurveyed by the proper officer, who ſhall accordingly make a perfect ſurvey, and certify the ſeveral particulars thereof; and ſuch collector and comptroller ſhall immediately tranſmit the ſaid certificate of ſurvey to the perſon authorized to regiſter ſhips and veſſels at the port to which ſuch veſſel belongs, who ſhall regiſter ſuch veſſel, and grant certificate of regiſtry; and it ſhall be lawful for the collector and comptroller, or other principal officer of the cuſtoms, in the port where ſuch ſhip or veſſel ſhall be ſo found, to detain her until a perfect and accurate ſurvey, in the manner hereinbefore directed, can be made.

The remaining ſections of this act relate to penalties upon the

the mifconduct of officers, forging or altering certificates of regiftry, mode of recovering penalties, &c.

By 27 G. III. c. 19. f. 4, no oath taken for the fole purpofe of acquiring the rights of a citizen or burgher in any foreign city or town in Europe, to be enjoyed during the time that fuch perfon taking fuch oath fhall refide in fuch city or town, and for a limited time after fuch refidence fhall have expired, fhall be deemed an oath of allegiance to a foreign ftate, nor inconfiftent with the form of the oath upon regiftry prefcribed by 7 & 8 W. III.

Ships belonging to the Eaft India company, or any other body corporate, are to be regiftered upon the oath fubfcribed by the fecretary of the faid company or other body corporate, or by any other officer properly authorized. f. 7.

No veffel whatfoever, not exceeding the burthen of 30 tons, and not having a whole or fixed deck, and being employed folely in the Newfoundland fifhery, or on the banks or fhores of the provinces of Quebec, Nova Scotia, or New Brunfwick, adjacent to the gulf of St. Lawrence, and to the north of cape Canfo, or of the iflands within the fame, or in trading coaftwife within the faid limits, fhall be fubject to be regiftered in purfuance of the faid act. f. 8.

Ships built in Newfoundland, and thofe parts of the provinces of Quebec, Nova Scotia, and New Brunfwick, adjacent to the gulf of St. Lawrence, and to the north of cape Canfo, or in the iflands within the faid limits, on account of owners refiding in his majefty's European dominions, fhall be regiftered in the above places, upon the hufbands or principal agents of the faid fhips taking the oath required; and fuch certificates fhall be of the fame effect as if granted upon the oath of the owners, until fuch time as they fhall arrive in port in any of his majefty's European dominions, where they may be refpectively regiftered upon the oath of the refpective owners, but no longer. And whenever fuch fhip fhall arrive at any fuch port in his majefty's European dominions, the certificates of regiftry, granted in purfuance of this act, fhall be null and void, and fhall be delivered up to be cancelled; and fuch fhips are hereby required to be refpectively regiftered *de novo* conformably to the requifitions of the preceding act. f. 9.

By 27 G. III. c. 19. f. 13, all fhips not regiftered according to the directions and regulations of the faid act, although fuch fhips may be owned by his majefty's fubjects, fhall be held and deemed as alien fhips, and fhall in all cafes be liable to fuch and the fame penalties and forfeitures as alien fhips are by law liable to in fimilar cafes.

By 34 G. III. c. 42, foreign fhips and veffels heretofore owned by fubjects of the late French king, which in confequence of any capitulation may be put under his majefty's protection at the time of, or in confequence of the furrender of any foreign colony, may be regiftered as fhips condemned as lawful prize, and fhall become entitled to the privileges of Britifh fhips, under the regulations and reftrictions hereafter mentioned. Provided always, that no fhip fhall be fo regiftered but upon producing a certificate under the hand and feal of the perfon who commanded in chief, by fea or land, at the time when fuch foreign colony was furrendered (or in cafe of the death or departure of any fuch officer before fuch certificate fhall have been fo given, then upon a like certificate under the hand and feal of the perfon who fhall command in chief, by fea or land, at fuch colony), teftifying that fuch fhip or veffel was put under the protection of his majefty at the faid time; and upon oath, hereinafter directed, being taken and fubfcribed before the perfon authorifed to make fuch regiftry, by the owner of fuch fhip, if fhe belong to one perfon only; or in cafe there fhall be two joint owners, then by both of fuch joint owners, if both be refident within 20 miles of the place where fuch regiftry is required, or by one of fuch owners, if one or both of them fhall be refident at a greater diftance; or if the number of fuch owners fhall exceed two, then by the greater part of them, if the greater number of them fhall be refident within 20 miles, not in any cafe exceeding three of fuch owners, or by one of fuch owners, if all fhall be refident at a greater diftance. Provided that fuch regiftry fhall, for the ifland of St. Domingo, be made at the port of Kingfton in the ifland of Jamaica, and for any of the French Leeward iflands, in the port of Rofeau in the ifland of Dominica; and the faid ports of Kingfton and Rofeau fhall refpectively, for the purpofe of fuch regiftry, be deemed to be the port to which fuch fhip belongs. f. 1.

His majefty, by the advice of his privy council, may at any time, on the arrival of any fuch fhip in Great Britain, upon application made to him, authorife any fuch fhip (without payment of any duty whatever for the faid fhip, or the fails and other neceffary tackle, apparel, and furniture thereof) to be regiftered, as in the cafe of a prize-fhip, in any port of Great Britain. f. 4.

No perfon heretofore a fubject of the late French king, being a white perfon, a mulatto, or free negro, fhall be employed to navigate any veffel bound from fuch foreign colony, to any part of his majefty's dominions, or be conveyed as a paffenger on board thereof, unlefs fuch perfon fhall produce a certificate under the hand and feal of the perfon who commands in chief in fuch foreign colony, or at the place therein whence fuch fhip fhall fail, teftifying that fuch perfon has taken the oath of fidelity and allegiance to his majefty; and no negro-flave belonging to any perfon whatfoever, heretofore a fubject of the late French king, fhall be fo conveyed or employed, but upon a certificate under the hand and feal of his mafter (which mafter fhall have taken the oath of fidelity and allegiance as aforefaid), certifying the good character of fuch negro-flave, and teftifying that his conduct has been fuch that he may be fafely admitted into the ports of his majefty's dominions; which certificate fhall be indorfed by the perfon who commands in chief his majefty's troops or veffels at the place from whence fuch fhip fhall fail, fignifying that he has no reafon to doubt of the truth thereof; upon pain that the mafter or commander of fuch fhip fhall forfeit 50*l.* for every perfon refpectively employed or conveyed in fuch fhip without having fuch certificate. f. 5.

By 34 G. III. c. 68, no goods, wares, or merchandizes whatever fhall, from the expiration of fix months after the conclufion of the prefent war, be imported into, or exported from, any port or place in Great Britain, or Guernfey, Jerfey, Alderney, Sark, or Man, to any other port or place of the fame, on board any fhip or veffel which, by law, is or fhall be required to be regiftered as a Britifh fhip or veffel, unlefs fuch fhip or veffel fhall be navigated by a mafter and three-fourths at leaft of the mariners Britifh fubjects. Nor, from the expiration of fix months from the conclufion of the prefent war, fhall any fhip or veffel, which by law is or fhall be required to be regiftered as a Britifh fhip or veffel, be navigated but by a mafter and three-fourths of the mariners at leaft Britifh fubjects, except as hereinafter provided. f. 1, 2, 3.

No goods, wares, or merchandizes whatever fhall be carried from any port in Great Britain, or Guernfey, Jerfey, Alderney, Sark, or Man, to any other port or place of the fame, nor fhall any fhip be permitted to fail in ballaft from or to any of the aforefaid ports, nor be employed in fifhing on the faid coafts, unlefs fuch fhip fhall be wholly and folely manned with and navigated by a mafter and mariners all Britifh fubjects. The commiffioners of the cuftoms may, however, by licence under their hands, authorife any fuch fhip or veffel employed in fifhing on the coaft of Great Britain, or of the iflands of Guernfey, Jerfey, Alderney, Sark, or Man, to have on board any foreign mariners for the purpofe of inftructing the Britifh mariners thereof in the art of fifhing; fuch foreign mariners not exceeding one-fourth of the number of mariners on board fuch veffel, except in cafes of ficknefs, death, defertion, or capture. f. 5.

By ftat. 34 G. III. c. 68, no perfon fhall hereafter be deemed to be qualified to be the mafter of a Britifh fhip, or to be a Britifh failor, feaman, or mariner, except the natural-born fubjects of his majefty, or perfons naturalized by any act of parliament, or made denizens by letters of denization; or except perfons who have become his majefty's fubjects by virtue of conqueft or ceffion of fome newly acquired country, and who fhall have taken the oath of allegiance to his majefty, or the oath of fidelity required by the treaty of capitulation, by which fuch newly acquired country came into his majefty's poffeffion, except as is hereinafter provided. f. 6.

But every foreign feaman ferving on board any of his majefty's fhips in time of war, for the fpace of three years, who fhall alfo take the oath of allegiance, fhall be entitled to be employed as a mafter of a Britifh fhip or veffel, or as a Britifh mariner on board any Britifh fhip, upon delivering certificates from the captains under whom he ferved, of the time he fhall have ferved, and of his faithful fervice and good behaviour, and a certificate of his having taken the oath of allegiance. f. 7.

No perfon who has taken an oath of allegiance to any foreign ftate fhall be deemed qualified to be the mafter of a Britifh fhip or veffel, or a Britifh failor, unlefs fuch perfon fhall have taken fuch oath of allegiance before he became fo qualified; and any perfon who fhall, after having become difqualified by taking fuch oath of allegiance, take the charge or command of any Britifh fhip or veffel, fhall for every fuch offence forfeit one hundred pounds; and if fuch perfon fhall engage to ferve as a Britifh feaman or mariner on board any fuch fhip, he fhall forfeit ten pounds, unlefs the owners fhall fhew that fuch difqualifications were unknown to them or their agents at the time of engaging fuch mafter or failor to ferve on board fuch fhip or veffel. Except in the navigation on the feas of America and the Weft Indies, any negroes belonging to his majefty's fubjects, and in the feas to the eaftward of the Cape of Good Hope, Lafcars and other natives of any of the countries to the eaftward of the Cape of Good Hope, may be employed as Britifh failors, feamen, or mariners, in manner heretofore practifed. Provided neverthelefs, that no negro belonging to any perfon who has become a fubject of his majefty, in manner before defcribed, in any of the iflands or colonies late under the dominion of the French, fhall be entitled to be employed in manner before mentioned as a Britifh failor, feaman, or mariner, unlefs all the conditions required by the 34th G. III. c. 42, fhall have been complied with during the continuance of the faid act.

By the 13th G. II. c. 3, his majefty in time of war may permit merchant fhips to be navigated by foreigners, provided one-fourth of the crew be Britifh fubjects.

If any goods, wares, or merchandize whatever fhall be imported or exported, or carried coaftwife, contrary to the provifions of this act, or any of them, all fuch goods, wares, and merchandize, and alfo the fhip or veffel, with all her guns, furniture, ammunition, tackle, and apparel, fhall be forfeited; and if any fhip fhall fail in ballaft, or fhall fail to be employed in fifhing along the coaft in manner herein before mentioned, or, being required to be manned and navigated with a mafter and a certain proportion of Britifh mariners, in manner herein before directed, fhall not be manned and navigated accordingly, fuch fhip or veffel, with all her guns, furniture, ammunition, tackle, and apparel, and all the goods, wares, and merchandize on board, fhall be forfeited. f. 10.

All goods, wares, and merchandize, and all veffels, forfeited by this act, may be feized by the commander of any of his majefty's fhips of war, or any commiffioned, warrant, or petty officer fpecially appointed, or by any officer or officers of his majefty's cuftoms or excife.

If any Britifh fhip fhall be found at fea, having on board a greater number of foreign mariners than is allowed by this act, or any law in force or hereafter to be made, and the mafter of fuch veffel fhall produce a certificate of the actual neceffity of engaging fuch foreign mariners in fome foreign port, by occafion of the ficknefs, death, or defertion of the like number of Britifh mariners, or of the fame having been taken prifoners during his voyage, and that Britifh mariners could not be engaged at fuch foreign port to fupply their place, and that for the fafe navigation of fuch fhip or veffel, it became neceffary to engage and employ fuch foreign mariners, under the hand of his majefty's conful at the foreign port where the mariners are fo engaged, or, if there be no fuch conful there, under the hands of two known Britifh merchants at fuch foreign port, no feizures fhall be made by the perfons authorifed under this act, nor fhall fuch fhips be molefted or detained at fea; but fuch perfons fhall indorfe the certificate fo produced, teftifying the production thereof, and when and where met with at fea, and that the number of foreign mariners correfpond with the certificate of fuch Britifh conful, or fuch known Britifh merchants, for the confideration and inveftigation of the commiffioners of his majefty's cuftoms in England and Scotland refpectively.

By 34 G. III. c. 68. f. 14, no transfer, nor agreement for transfer, of the property in any fhip or veffel, either in whole or in part, fhall be made but by a bill of fale or inftrument in writing, which fhall contain a recital in words at length of the certificate of regiftry.

If a fhip be at fea at the time when the transfer is made, fo that an indorfement and certificate cannot be immediately made, the fale, or contract for fale, fhall, notwithftanding, be made by fome inftrument in writing, and a copy thereof fhall be delivered to the perfon authorifed to make regiftry, who is to indorfe an entry thereof on the oath or affidavit, make a memorandum in the book of regifters, and give notice to the commiffioners of the cuftoms as before directed: and within ten days after the fhip returns to port, an indorfement fhall be made on the certificate of regiftry, and a copy thereof delivered as before-mentioned; otherwife fuch fale fhall, to all intents and purpofes, be void. f. 16.

Where the owner of any fhip fhall, at the time of transferring the property in any fhips, be abroad, fo that an indorfement, &c. or fuch bill of fale, cannot be immediately made, the fame may be done at any time within fix months after fuch transfer, in which cafe, within ten days after the arrival of the owner or his agent in this kingdom, (if the fhip be in any port thereof, and if not, within ten days after fuch fhip's arrival) an indorfement on the certificate of regiftry fhall be made, &c. as before directed. f. 17.

Mafters of fhips refufing to deliver up the certificate of regiftry to the proper perfon empowered to make regiftry, upon being required fo to do by the owner or owners, or the major part of the owners, (if fuch mafter have not any property

perty

perty therein,) or by the other owner or owners, or major part thereof, (if ſuch maſter have any ſhare therein,) and upon oath being made by ſuch owner, owners, or major part thereof, before any juſtice of the peace near where ſuch refuſal ſhall be, ſuch juſtice may grant his warrant to bring the maſter before him; and if it ſhall appear that the ſaid certificate is *wilfully* detained, ſuch maſter ſhall pay one hundred pounds, and on failure of payment ſhall be committed to the common gaol, for not leſs than ſix months, nor more than twelve. ſ. 18.

Upon the juſtice's certifying the above *wilful* refuſal of the maſter of any veſſel to deliver up the certificate to the perſon authoriſed to make regiſtry, he ſhall regiſter the ſaid ſhip *de novo*, the terms and conditions of the law being complied with. ſ. 19.

When property in any ſhip or veſſel belonging to any of his majeſty's ſubjects ſhall be transferred by ſale, and ſuch veſſel ſhall be required to be regiſtered *de novo*, it ſhall not be done unleſs there be produced to the regiſter, the bill or other inſtrument of ſale. Provided always, that the commiſſioners of cuſtoms, and the governor, lieutenant-governor, or commander-in-chief for the time being of the iſlands of Guernſey or Jerſey, or of any colony, plantation, iſland, or territory belonging to his majeſty, may, upon due conſideration of the particular circumſtances of the caſe, give directions for the regiſtering ſuch veſſel *de novo*, and granting a certificate of ſuch regiſtry, notwithſtanding ſuch bill or other inſtrument of ſale ſhall not have been produced as aforeſaid; and ſuch regiſtry ſhall be made, and ſuch certificate thereof ſhall be accordingly granted, if all the other regulations required by the laws in force concerning the regiſtry of ſhips *de novo* be complied with. ſ. 20.

If there ſhall be any alteration of property at the ſame port, and the owner ſhall be deſirous of having the ſhip regiſtered *de novo*, ſuch ſhip may be ſo regiſtered, provided all the rules, regulations, and conditions are complied with relative to veſſels regiſtered *de novo*. ſ. 21.

In caſe of any transfer of property in any ſhip whilſt at ſea, ſuch ſhip ſhall proceed directly to the port for which the cargo then on board is deſtined, and ſhall ſail from thence to the port of his majeſty's dominions to which ſhe belongs, or to any other ſuch port in which ſhe may be legally regiſtered; and ſuch ſhip may take on board in the port for which her original cargo was deſtined, or in any other port in the courſe of her voyage home, ſuch cargo as may be legally carried to ſuch port of his majeſty's dominions where ſhe may be ſo regiſtered *de novo*. And if ſuch transfer of property ſhall be made while ſuch ſhip is in any foreign port, as ſoon as the maſter of ſuch ſhip ſhall become acquainted therewith, ſuch ſhip, after having delivered the cargo then on board at the port for which ſhe is deſtined, ſhall ſail thencefrom to the port to which ſhe belongs, or to any other ſuch port in which ſhe may be legally regiſtered; and may take on board at the port for which her original cargo was ſo deſtined, or at any other port in the courſe of her voyage home, ſuch cargo as may be legally carried to ſuch port of his majeſty's dominions where ſhe may be ſo regiſtered *de novo*. And if ſuch transfer of property ſhall be made while ſuch ſhip is on a fiſhing voyage, as ſoon as the maſter of ſuch ſhip ſhall become acquainted therewith, ſuch ſhip, after having finiſhed ſuch fiſhing voyage, without touching at any foreign port, except for the purpoſe of repairs or refreſhments, or for delivering any part of her cargo, ſhall ſail to the port of his majeſty's dominions to which ſhe belongs, or to any other ſuch port where ſhe may be legally regiſtered, and may take on board at the foreign port or ports laſt deſcribed, or at any other ports in the courſe of her voyage home, ſuch cargo as may be legally carried to ſuch port of his majeſty's dominions; and every ſuch ſhip as aforeſaid ſhall be regiſtered *de novo*, as ſoon as ſhe returns to the port of his majeſty's dominions to which ſhe belongs, or to any ſuch port in which ſhe may be legally regiſtered by virtue of the ſaid act; on failure whereof ſuch ſhip ſhall be deemed from thenceforth to be a foreign ſhip or veſſel, and ſhall not again be regiſtered, or be entitled to the privilege of a Britiſh ſhip or veſſel, unleſs upon ſpecial repreſentation of the circumſtances of the caſe to the commiſſioners of cuſtoms, or to the governor, lieutenant-governor, or commander-in-chief for the time being of the iſlands of Guernſey or Jerſey, or of any colony, plantation, iſland, or territory to his majeſty belonging, as the caſe may be: provided nevertheleſs, that in no caſe the ſhip or veſſel of which the property is ſo transferred, ſhall be entitled to the privileges of a Britiſh ſhip or veſſel, unleſs ſhe ſhall return to the port to which ſhe belongs, or to ſuch other port in which ſhe may be regiſtered *de novo*, within the period of twelve months after the date of ſuch transfer of property, if ſuch ſhip ſhall not be on a voyage to the eaſt of the Cape of Good Hope, or to the weſt of cape Horn; or within two years, if the ſhip is on the above voyages at the time ſuch transfer of property ſhall take place, except by the order of the ſaid commiſſioners, governor, lieutenant-governor, or commander-in-chief reſpectively. ſ. 22. See *Marine* Insurances, and Policy.

REGIUS Professors. King Henry VIII. founded five lectures in each of our univerſities: *viz.* of Divinity, Hebrew, Greek, Law, and Phyſic; the readers of which lectures are in the univerſity ſtatutes called *regii profeſſores*.

Regius, in *Medicine*. See Jaundice.

REGLE *de l'Octave*, Fr., a rule for accompanying the octave aſcending and deſcending in the baſe; giving to each note of the ſcale its appropriate harmony in every key. This rule, well known and practiſed in the 24 keys, major and minor, will enable ſtudents in thorough-baſe to figure a baſe themſelves, and to accompany modern muſic without figures.

It is diſputed in France who was the inventor of this rule: Rameau and Rouſſeau aſſign it to De Laire, M. Laborde to Campion. "This formula," ſays Rouſſeau, "was firſt publiſhed by De Laire in 1700." If this date could be aſcertained, it would remove all doubts concerning the author of the rule; as Campion's "Treatiſe of Accompaniment" is not pretended to have appeared till after 1705.

This rule aſcertains what chords or harmony belong to every diatonic movement of the baſe, aſcending and deſcending. See Accompaniment, or Thorough-base; where the baſe will be figured, and the chords written over it. We confine the infallibility of this rule to modern muſic, as no proviſion is made for 4ths and 9ths, which ſo frequently occur in Corelli, Geminiani, and Handel. But theſe diſcords, and ſeveral other combinations, are conſidered in the articles Counterpoint and Accompaniment, or *Thorough-baſe*; which ſee.

By this formula it will appear, that to the key-note there is always a common chord; to the 2d of the key, a $^{6}_{3}$; to the 3d of the key, a 6th; to the 4th of the key, a $^{6}_{5}$; to the 5th of the key, a common chord. Thus far the chords are rigorouſly in one key; but in order to connect the 6th to the 5th, Rameau gives the chord of the $^{6}_{3}$ to the 6th, as in deſcending, which makes it the 2d of a new key; but then to recover the modulation into the original key, he gives $^{6}_{5}\natural$ to the 7th or *note ſenſible* of the key, and then terminates

minates the fcale by a common chord to the octave of the key-note.

In defcending, it is neceffary to imagine the harmony in the 5th of the key for the four firft notes: as, fuppofing the fcale to be in C major, after repeating the common chord to the octave, the 7th of C muft be regarded as 3d of the key of G, and be only accompanied by the 6th. A, as 2d of G, by a $\substack{6\\4\\3}$, as in afcending; and the 5th of the key by a common chord, or clofe in G. The 4th of the key in defcending has a $\substack{6\\4\\2}$, or chord of the 5th of the key repeated; the next three chords are the fame as in afcending.

In minor keys, in all which fuppofing A natural to be the archetype, the chords are much the fame; only whenever the 7th of the key is wanting in the afcending fcale, it muft be accidentally fharp: as to A, a common chord minor; to B, the 2d of the key, a $\substack{6\\4\\3}$; to the 3d of the key, a 6th; to the 4th, a $\substack{6\\5}$; to the 5th, a common chord, with a fharp 3d; to the 6th, if natural, a 6th; if fharp, a $\substack{6\\4\\3}$; to the 7th fharp, $\natural\substack{6\\5}\natural$, and a common chord to the octave.

In defcending, to the 7th natural, a 6th; to the minor 6th, a $\substack{3\\3}$, or 6 doubling the 3d; to the 5th of the key, a fharp 3d; to the 4th of the key, the fame chord, or $\substack{6\\4\\2}$; and to the three laft, the fame as in afcending.

Thefe chords will be more clearly comprehended in notation on the thorough-bafe plates, to which we refer.

Though the regle de l'octave only provides for the regular afcent and defcent of the bafe in plain counterpoint, we know, by long experience, that it teaches more thorough-bafe and counterpoint in a fhort time, than any other rule that has been propofed fince the laws of harmony were fettled. See Thorough-base, Accompaniment, and Composition.

REGLET, or Riglet, in *Architecture*, a little flat narrow moulding, ufed chiefly in compartiments, and pannels, to feparate the parts or members from one another, and to form knots, frets, and other ornaments.

The word is a diminutive of the French, *regle, rule.*

The reglet, according to Daviler, differs from the *fillet* and *liftel*, in that it projects equally, like a ruler.

Reglets, or *Riglets*, in *Printing*, are thin rulers, or flips of wood, of different dimenfions, placed in the chafe, between the pages, and at the extremes of them, to keep them afunder, and to hold them tight.

The reglets make the chief part of what they call *the furniture of the chafe*. See Chase.

They are particularly denominated from the place they hold in refpect of the pages, *head-flicks, gutter-flicks,* &c.

The term reglets is alfo ufed abroad for a ruler of metal, three quarters of an inch long, but which may be lengthened out by joining feveral together; ufed to feparate the columns, in books that have feveral in the fame page; as alfo for lines to place the notes on, in printing of mufic. See Printing.

Reglet is alfo ufed for a little thin flip of wood, occafionally, though feldom, ufed by compofitors for the prefs to take off the lines from the compofing-ftick, and place them on the galley, where the lines are of an extraordinary length: and where the lines are at great diftances, thofe diftances are made by leaving a reglet between each line, when printed.

REGMALARD, in *Geography*, a town of France, in the department of the Orne; 9 miles E.N.E. of Belefme.

REGNANO, a town of Naples, in Capitanata; 16 miles from Manfredonia.

REGNANT Queen. See Queen.

REGNARD, John-Francis, in *Biography*, a French poet and writer of comedy, was born of a good family, at Paris, in 1647. His earlieft paffion was that for travelling, and he firft made the tour of Italy. On his return, in an Englifh fhip, the veffel was taken by the Algerines, and the crew made flaves at Algiers. Regnard, by his fkill in cookery, ingratiated himfelf with his mafter: he poffeffed another art, which had nearly proved fatal to him. His perfon and manners recommended him to the attention of the ladies, whofe advances he encouraged, and being difcovered, the alternative was given him of being burnt to death or becoming a difciple of the Koran. He was, however, releafed from this difficulty by the interpofition of the French conful, and the proper application of a confiderable bribe. He gained his liberty, and returned to France, and in 1681 departed upon a new tour to the northern countries of Europe. After an abfence of three years he came back to Paris, and fettled quietly, with the view of cultivating his tafte for literary purfuits. He compofed a number of comedies for the French theatre, which were acted with fuccefs, and which, in the general opinion, placed him next to Moliere in true comic humour. Gaiety is the predominant character of Regnard's comedies, which is fometimes maintained at the expence of morality. He excelled not lefs in the elevated or genteel comedy, than in the low, or familiar. His two beft pieces are faid to be "Le Joueur," and "Le Legataire;" for defcribing, to the life, the fcenes of the firft, he was extremely qualified, being himfelf a lucky gamefter. He wrote eight comedies, fome pieces for the Italian theatre, and an opera. He alfo publifhed mifcellaneous poems, confifting of fatires, epiftles, &c. In profe he gave a relation of his travels, of which the only part that excited much intereft was his account of Lapland. Regnard died at the age of 62. His works have been printed collectively, of which the beft edition is that of Paris, in 1790, in 4 vols. 8vo.

REGNAVADSOE, in *Geography*, a fmall ifland in the North fea, near the coaft of Norway. N. lat. 69° 50′.

REGNI, in *Ancient Geography*, a name given to the ancient inhabitants of Surrey and Suffex, and perhaps of part of Hampfhire. They were feated E. of the Belgæ, and S. of the Atrebatii. As thefe people poffeffed fo large a tract of the fea-coaft in the fouth part of this ifland, it is very probable that they had come from the continent, and fettled here not very long before the Roman invafion, perhaps at the fame time with their neighbours the Belgæ. The Belgæ and the Regni had been near neighbours on the continent; the one having migrated from the country of the Sueffiones, now Soiffons, and the other from the country of the Rhemi, now Reims. The Regni, like all the other Belgic Britons, early fubmitted to the Roman power, and continued fteady in their obedience, without engaging in any revolt. It is not known who was fovereign of the Regni when they fubmitted to the Romans, but foon after their fubmiffion, they were put under the government of Cogidunus, king of the Dobuni. For this prince, who was then very young, had got fo much into favour with the emperor Claudius, and his minifters, that he was not only allowed to keep his own dominions, but he had feveral other neighbouring ftates put under his authority. It feems probable, from a famous infcription difcovered at Chichefter, that Cogidunus governed the Regni in quality of the emperor's lieutenant, or legatus Augufti; for in that infcription he is fo ftyled. He continued a faithful and ufeful friend and ally to the Romans above 60 years, and thus he was fo much endeared to them, that

that, according to their cuftom in other countries, they permitted his pofterity to fucceed him, perhaps for feveral generations. Although the Regni were very early and very obedient fubjects of the Roman empire, yet as they were long after under the immediate government of Britifh princes, few of the Romans feem to have fettled among them. This is, without doubt, the reafon that we meet with fo few veftiges of thofe great and active people in thofe countries which were anciently inhabited by the Regni. Chichefter was certainly a confiderable place in the time of the Romans, and probably the capital of the Regni, which led the Romans to call it Regnum. However, Camden, Gale, Baxter, and others, are unanimous in fixing Regnum, the capital of the Regni, at Ringwood; but Mr. Horfley has produced feveral reafons for fuppofing it to have been fituated where Chichefter now ftands. The Neomagus of Ptolemy, and the Noviomagus of the Itinerary, was a city of the Regni, and it is generally placed at Woodcote, near Croydon, in Surrey; though Mr. Baxter and fome other antiquaries contend for Ravenfham, in Kent. In the moft perfect ftate of the Roman government in Britain, the country of the Regni made a part of the province called Flavia Cæfarienfis, and was governed by the prefident of that province.

REGNIER, Mathurin, in *Biography*, a French poet, was born at Chartres in 1573. He is faid to have difplayed, at a very early period, a great propenfity to fatire, which his father in vain attempted to reprefs by chaftifement. The exercife of his fatirical talents procured him patrons, among whom were the cardinal Francis de Joyeufe, and Philip de Bethune, both of whom he accompanied to Rome. By the intereft of thefe great men he received confiderable preferment in the church, but the dignity and gravity of the clerical character was no reftraint upon his pleafures, and he died at the age of forty, worn out with licentious practices. The works of Regnier confift of fatires, epiftles, elegies, ftanzas, odes, &c.: of thefe his fatires are moft efteemed, and they were thought to make a kind of epoch in French poetry. The poems of Regnier have been frequently printed; the beft editions are thofe of Rouen, 1729, and of London, 1734, with remarks.

REGNIER-DESMARAIS, Francis-Seraphin, a French author of confiderable reputation, was born at Paris in 1632, of a family originally from Saintonge. Being the younger fon of a numerous family, he had to depend folely upon his own exertions for making his way in the world, and he fucceffively attached himfelf to feveral perfons of rank, whom he accompanied in their travels. Making a proper ufe of his opportunities, he acquired a knowledge of the Italian and Spanifh languages, and he became fo much a mafter of the former, that when he attended the duke of Crequi on his embaffy to Rome, in 1662, he wrote the official letters in Italian with fo much purity, that they were not known to be the compofitions of a foreigner. But he obtained a ftill greater triumph, by paffing upon the academicians of Della Crufca one of his own odes for a newly difcovered piece of Petrarch. In confequence of this he was elected, in 1667, a member of that celebrated academy. At the age of thirty-fix he took ecclefiaftical orders, for the purpofe of enjoying a priory given him by Lewis XIV., as a recompence for his public fervices, and in 1670 he was admitted a member of the French Academy, in the hope that he might become a contributor in the compilation of their dictionary. Soon after this, at the requeft of the Jefuits, he tranflated from the Spanifh language a treatife "On Chriftian Perfection." In his capacity of academician, Regnier difplayed fo much activity and zeal, that on the death of Mezerai, in 1684, he was appointed to fucceed him as fecretary. When the dictionary was completed, the fecretary by order of the Academy, drew up a preface, and an epiftle dedicatory to the king; but, during his abfence, other members, who were infpired with the defire of emulating him in this honour, procured a preference for their own productions. This difappointment drew from Regnier fome critical remarks upon the rival performances, tinged with that cavilling and difputatious fpirit, to which it appears he fo often gave way, that he obtained the title of the abbè Pertinax. He was fo attached to his own opinion, that he could feldom be prevailed upon to give up his point, or to drop a difpute. Fontenelle, being once prefent at an academical difcuffion, in which Regnier was warmly engaged, exclaimed, "this is a difpute that might be prevented from ever ending, and therefore it ought to be ended immediately." Regnier obtained feveral benefices, and would probably have been promoted to the very higheft dignity in the church, had he not been fufpected of tranflating a fcene in the "Paftor Fido," which feems to inculcate a licentious morality, and likewife fufpected of writing a ftill more objectionable copy of verfes. He was occafionally employed in public bufinefs. He died at Paris in 1713, at the age of 81. He had drawn up a great many of the moft important articles in the dictionary of the French academy, and he publifhed, as the refult of his long ftudy of the principles of the French language, his "Grammaire Françoife," in 2 vols. 12mo., which is confidered as a very valuable performance. His other works in profe were "L'Hiftoire des Dèmeles de la France, avec la Cour de Rome, au Sujet de l'Affaire des Corfes." Tranflations of feveral of Cicero's pieces. In verfe he gave an Italian verfion of the Odes of Anacreon, and mifcellaneous poems in Latin, French, Italian, and Spanifh. His French poems are varied, ingenious, and well turned, but they are allowed not to poffefs much fire or force. We have alluded to the abbe's unyielding difpofition: but it muft be added, that he was ftedfaft in his friendfhips, inflexibly upright, and fcrupuloufly veracious. The laft quality, fays his biographer, he nobly expreffed, when, on being urged to violate the truth in favour of a man in power, and under the penalty of lofing his friendfhip, he faid, "I had rather quarrel with him than myfelf."

REGNO, in *Geography*, a town of Sweden, in Eaft Gothland; 28 miles N. of Nordkioping.

Regno, *Ne exeat*, in *Law*. See Ne *exeat*, &c.

REGNUM. See Regni.

Regnum *Ecclefiafticum*, a denomination given to one of the two kingdoms, which the clergy fuppofed to have exifted in fome countries: this, they pretended, was abfolute and independent of any but the pope, comprehending ecclefiaftical men and caufes, and exempt from the fecular magiftrate: the other was a *regnum feculare* of the king or civil magiftrate, which was fubordinate and fubject to the ecclefiaftical kingdom: but thefe ufurpations were exterminated here by Henry VIII. 2 Hale's Hift. P. C. 324.

REGNY, in *Geography*, a town of France, in the department of the Rhône and Loire; feven miles E. of Roanne.

REGOLA, Ital., a rule in mufic, a canon.

Regola *Armonica*, a monochord.

REGOLETS, in *Geography*, a paffage from the gulf of Mexico into lake Pontchartrain, about ten miles long, and three or four hundred yards wide.

REGRADATION, Regradatio. See Degradation.

REGRATOR, Regratarius, a law-word, formerly ufed for one that bought wholefale, or by the great, and fold again by retail.

The

The term is now chiefly used, as it is described by stat. 5 & 6 Edw. VI. cap. 14. to denote one that buys corn, or other dead victuals, in any market, and sells them again, in the same market, or within four miles of the place.

Regrating is an offence against the public, and is liable, by the statute just cited, to the same penalty with engrossing and forestalling.

REGRATOR is also used for a person who furbishes up old moveables, to make them pass for new. See FRIPPERY.

Among masons, &c. to regrate is to take off the outer surface of an old hewn stone, with the hammer and ripe, in order to whiten and make it look fresh again.

REGRESSION, or RETROGRADATION of curves, &c. See RETROGRADATION.

REGUINY, in *Geography*, a town of France, in the department of the Morbihan; five miles N.W. of Josselin.

REGULA. See RULE.

REGULA, in *Architecture*. See REGLET.

REGULAR, REGULARIS, denotes the relation of any thing that is agreeable or conformable to the rules of art.

In this sense, the word stands opposed to *irregular*, or anomalous.

Thus we say, a regular proceeding, a regular building, regular poem, regular verb, &c.

REGULAR *Figure*, in *Geometry*, is a figure which is both equilateral and equiangular; *i. e.* whose sides, and consequently its angles, are all equal.

The equilateral triangle and square are regular figures. All other regular figures, consisting of more than four sides, are called regular polygons.

Every regular figure may be inscribed in a *circle*; which see.

For the dimensions, properties, &c. of regular figures, see POLYGON.

REGULAR *Body*, called also *Platonic body*, is a solid terminated on all sides by regular and equal planes, and whose solid angles are all equal.

The regular bodies are five in number; *viz.* the *cube*, which consists of six equal squares; the *tetrahedron*, or regular triangular pyramid, having four equal triangular faces; the *octahedron*, having eight; the *dodecahedron*, having twelve pentagonal faces; and the *icosahedron*, having twenty triangular faces. See each under its proper article. Besides these five, there can be no other regular bodies in nature.

To measure the surface and solidity, &c. of the five regular bodies.—The solidity, &c. of the cube is shewn under the article CUBE. The tetrahedron being a pyramid, and the octahedron a double pyramid; and the icosahedron consisting of twenty triangular pyramids; and the dodecahedron of twelve quinquangular ones, whose bases are in the surface of the icosahedron and dodecahedron, and their vertices meeting in a centre; the solidities of these bodies are all found from what we have shewn under PYRAMID.

1. Their surface is had by finding the area of one of the planes, from the lines that bound it; and multiplying the area thus found by the number from which the body is denominated: *e. gr.* for the tetrahedron, by 4; for the hexahedron, or cube, by 6; for the octahedron, by 8; for the dodecahedron, by 12; and for the isocahedron, by 20. The product is the superficial area.

Or, the superficial contents of any of the five Platonic bodies may be had by the following proportion; as 1 is to the square of the side of the given Platonic body,

$$\text{so is} \left\{ \begin{array}{l} 1.7320508 \\ 3.4641016 \\ 6.0000000 \\ 8.6602540 \\ 20.6457788 \end{array} \right\} \text{to the superficial content of the} \left\{ \begin{array}{l} \text{tetrahedron.} \\ \text{octahedron.} \\ \text{hexahedron.} \\ \text{icosahedron.} \\ \text{dodecahedron.} \end{array} \right.$$

Hence we have the following rule: multiply the proper tabular area, taken from the preceding table, by the square of the side of the given solid, for the superficies.

2. The diameter of a sphere being given, to find the side of any of the Platonic bodies, that may be either inscribed in the sphere, or circumscribed about the sphere, or that is equal to the sphere.

As 1 is to the number in the following table, respecting the thing sought, so is the diameter of the given sphere to the side of the Platonic body sought.

The diameter of a sphere being unity, the side of a	That may be *inscribed* in the sphere, is	That may be *circumscribed* about the sphere, is	That is *equal* to the sphere, is
Tetrahedron	0.816497	2.44948	1.64417
Octahedron	0.707107	1.22474	1.03576
Hexahedron	0.577350	1.00000	0.88610
Icosahedron	0.525731	0.66158	0.62153
Dodecahedron	0.356822	0.44903	0.40883

3. The side of any of the five Platonic bodies being given, to find the diameter of the sphere, that may be inscribed in that body, or circumscribed about it, or that is equal to it. As the respective number, in the above table, under the title, *inscribed*, *circumscribed*, or *equal*, is to 1, so is the side of the given Platonic body to the diameter of its inscribed, circumscribed, or equal sphere, in solidity.

4. The side of any of the five Platonic bodies being given, to find the side of either of the Platonic bodies, which are equal in solidity to that of the given body. As the numbet under the title *equal*, against the given Platonic body, is to the number under the same title, against the body whose side is sought, so is the side of the given Platonic body to the side of the Platonic body sought.

5. To find the solid contents of any of the five Platonic bodies. As 1 is to the cube of the side of any of these bodies, so is 0.1178513 to the solid content of a tetrahedron, 0.4174045 to that of the octahedron, 1.0000000 to that of the hexahedron, 2.1816950 to that of the icosahedron, and 7.6631189 to the solid content of the dodecahedron.

Hence we have the following rule: multiply the tabular solidity by the cube of the side or linear edge, for the solid content. The demonstration of this rule, and that for the superficies above given, is as follows:

The tabular numbers denote the surface and solidity of each body, when its side or edge is one; and, because, in similar bodies, the surfaces are as the squares of the linear edges, and the solidities as the cubes of the same, the truth of the rules is manifest.

If one of these bodies be required to be cut out of the sphere of any diameter, let $d\,r$ (*Plate* XII. *Geometry*, *fig.* 9.) be the diameter of any sphere, and $d\,a$ one-third of it, $= a\,b = b\,r$. Erect the perpendiculars $a\,e$, $c\,f$, and $b\,g$; and draw $d\,e$, $d\,f$, $e\,r$, $f\,r$, and $g\,r$; then will (1) $r\,e$ be the side of the tetrahedron; (2) $d\,f$, the side of the hexahedron; (3) $d\,e$, the side of the octahedron; (4) and cutting $d\,e$ in extreme and mean proportion in h, $d\,h$ will be the side of the dodecahedron; (5) setting the diameter $d\,r$ up perpendicular at r, from the centre c, to its top, draw the line $c\,g$, cutting

cutting the circle in g, let fall the perpendicular $g\ b$; fo is $b\ r$ the fide of the icofahedron.

REGULAR *Curve.* See CURVE.

REGULAR *Architecture*, *Fortification*, &c. See ARCHITECTURE, and FORTIFICATION.

REGULAR *Attacks*, in a fiege, are thofe that are made in form, or by regular approaches. See PARALLELS.

REGULAR *Baftion.* See BASTION.

REGULAR *Place.* See PLACE.

REGULAR, in the *Monaftic Senfe*, denotes a perfon who has made the vows in fome religious houfe. See RELIGIOUS and VOW.

Under regulars are comprehended the whole body of monks, friars, and mendicants, &c.

The denomination of regulars, in this cafe, arifes hence, that they are bound to obferve the regula or rule of the order they are entered into. Hence,

REGULAR *Prieft* is ufed for a prieft who is in fome religious order, in oppofition to a *fecular* prieft, who lives in the world, or at large.

A cardinal is reputed both regular and fecular, and is intitled to the privileges of both ftates.

Regulars may be promoted to bifhoprics and archbifhoprics, as well as feculars; but their promotion fecularizes them; the epifcopal dignity difpenfing them from the obfervation of the rule of which they had before made profeffion.

REGULAR *Abbots.* See ABBOT.

REGULAR *Benefices*, are fuch as can only be held by monks or religious; or at leaft, *per cupientem profiteri*, by a perfon defirous to embrace the monaftic life. See BENEFICE.

It is a maxim in the Romifh canon law, *regularia regularibus*, *i. e.* regular benefices are to be conferred on regular priefts. The abbeys that are chiefs of their refpective orders are all regular, and can only be ferved by monks and cardinals. All benefices are prefumed to be fecular, unlefs they be proved regular.

Anciently the regular benefices were almoft all conferred by way of adminiftration or curacy; the religious incumbents being always *ad manum* to their fuperiors, who difplaced them at pleafure. Hence the common maxim among the canonifts, *omne beneficium regulare manuale.*

The benefices appropriated to regulars are abbeys, conventual priories, fimple priories, and clauftral offices. They may be conferred on feculars *in commendam.*

REGULAR *Canons.* See CANON.

REGULAR *Places*, are thofe within the boundary or inclofure of the convent; as the cloifter, dormitory, chapter, and refectory. In oppofition to thofe deftined for guefts, and for the neceffaries of the houfe, which are reputed without the inclofure.

REGULAR *Corporation.* See CORPORATION.

REGULATION, a rule or order prefcribed by a fuperior, for the uniform and orderly management of fome branch of policy, juftice, or the like.

REGULATOR *of a Watch*, is a fmall fpring belonging to the balance, ferving to adjuft the going, and to make it go either fafter or flower.

REGULATOR *of Velocity*, in *Mechanics*, is a contrivance for regulating or governing the motion of a mill, or other large machine, by means of which it will always be caufed to preferve an equable and regular velocity in the motion of its parts, notwithftanding any accidental increafe of the moving force, or decreafe of the refiftance that may occafionally arife. A regulator muft be connected with fome lever, or other parts of the machine, which commands the fupply of whatever conftitutes its moving force, as the fhuttle of a water-wheel, the fail-cloth of a wind-mill, or valve of a fteam-engine; and it fhould have the property of acting fuddenly upon this lever, or other part, the inftant any increafe or decreafe of velocity in the motion takes place, either to elevate or deprefs it, and thus regulate the fupply in a degree proportioned to the quantity of alteration in the velocity; and it is by the fenfibility and accuracy of the regulator in this refpect that its perfection is eftimated.

The regulator moft commonly ufed is called a *governor.* This confifts of two or more pendulums fufpended from joints, which are fupported upon a vertical axis: this being caufed to revolve by the machine, and the pendulums accompanying it, the balls will, by the centrifugal force, recede from the axis or centre a quantity proportioned to the velocity of the motion and length of the pendulum: then, on any acceffion of the motion, they recede ftill further from the axis, or *vice verfâ*, if the velocity diminifhes. This motion is contrived to actuate the lever which regulates the velocity of the machine in a fteam-engine: it is connected with the valve which admits the fteam from the boiler to the cylinder, in a water-wheel with the fhuttle, through which the water flows, or in a wind-mill with the mill-ftones, or fail-cloths. See a farther defcription under MILL-WORK, STEAM-*Engine*, and WINDMILL.

The principle of the governor is the fame with the circular or conical pendulum, of which Huygens has laid claim to the invention, as well as of the long pendulum for regulating clocks, who fays he difcovered it nearly at the fame time as the other. The conical pendulum circulates feconds when of the fame length with the common pendulum, which will vibrate only half feconds. To explain it, we muft fuppofe a ball or weight to be fufpended by a ftring or rod, fo that the ball can defcribe in a horizontal circle by a motion of the rod round a vertical axis, with which the centre of fufpenfion coincides. In this motion the rod of the pendulum will defcribe the furface of a cone, of which the point of fufpenfion is the vertex, and the horizontal circle which the ball defcribes is the bafe: it is hence called the circular or conical pendulum. The ball has liberty to recede from, or approach to, the axis, by moving upon its centre of fufpenfion, and thus the circle the ball defcribes will be enlarged or diminifhed; and it is this circumftance which gives it the property of circulating or performing a revolution always in the fame fpace of time which a fimple pendulum of four times the length would vibrate; for this takes place equally whether the ball is extended to defcribe a large circle, or retracted to revolve in a fmall one; though, it fhould be obferved, that this is only true in the fuppofition that the pendulum-ball, in moving from the vertical axis upon its centre, will defcribe a parabola inftead of a circle, in the fame manner as the ball of a common pendulum is required to move in the arc of a cycloid inftead of a circle, to caufe all the vibrations, both long and fhort, to be performed in equal fpaces of time. Mr. Martin has, in his Inftitutions, given a very complete explanation of the principle of this pendulum, by fuppofing an inverted parabola, with its axis placed in a vertical pofition; then fuppofing a bowl or veffel excavated by the revolution of this figure upon its axis a paraboloid will be formed. A heavy globe or ball being put in this bowl, may, by agitating the veffel, be caufed to perform a revolution in a horizontal circle within the veffel, and it will be found to circulate in the fame period of time, whether it defcribes a fmall circle near the bottom of the veffel, or a large circle in its upper part, where the diameter is larger.

The

The governor or flying-ball is the regulator moft generally ufed in machinery, although there are other means which, in particular inftances, are preferable, from the circumftance of their poffeffing a greater power to operate upon the regulating part of the machine. One of thefe, called the water-regulator, confifts of a pump, which, being worked by the machine, will raife water into a ciftern, from which a conftant ftream flows off by a pipe and cock; a float is placed upon the furface of the water in the ciftern, and this communicates with the fteam-valve of the engine, or fhuttle of the water-wheel. The operation of this regulator is eafily explained, for the pump will raife a quantity of water exactly proportioned to the velocity of the machine, or the number of ftrokes it makes; whereas the ftream which flows off by the cock is a conftant quantity, and equal to that which the pump will fupply when the machine moves with its intended velocity. When this is the cafe, the furface of water in the ciftern will ftand at the fame height; but if the velocity is increafed, the pump will raife more water into the ciftern than the pipe and cock will carry off, and the furface rifing, elevates the float, which, by its action to diminifh the fupply of power to the machine, will correct the acceleration which has taken place in its velocity. The oppofite effect takes place if the velocity decreafes, *viz.* that the fupply to the ciftern being diminifhed whilft the efflux is conftant, the furface will fink, and the float defcending, opens the valve or fhuttle, and increafes the fupply of power to the machine until it regains the original velocity. The great advantage of this regulator is, that it can fo readily be made to keep the machine fteady at any velocity which may be required, and this by merely opening or clofing the cock: thus, if it is opened to carry off a greater quantity, the furface will fubfide, and the float, by defcending, opens a greater fupply of power to the machine, and occafions it to move quicker; but this, though it raifes more water by means of the pump, will not raife the furface of the water in the ciftern to fo great a height as it ftood at before, becaufe the efflux is now equal to the increafed fupply.

In all cafes this regulator will caufe the machine to work at fuch a rate, as to make the pump raife the fame quantity of water as the cock emits, and its rate may be afcertained before it is put to work; for if the quantity of water which the cock will difcharge in a minute, or other given fpace of time, is known, and the dimenfions of the pump; then it may eafily be calculated what number of ftrokes *per* minute the pump muft make to raife an equal quantity of water. The fenfibility of this regulator will be increafed by making the ciftern of a fmall fize, becaufe then any deviation from the intended rate of working will caufe the greater elevation or depreffion of the furface, and a greater action on the float: and, for the fame purpofe, it is beft to make the ciftern gradually diminifh in area, fo as to be fmaller both towards the top and at the bottom, than at the place where the furface is expected to ftand when the machine moves with the proper velocity. By this means it will rife or fall more rapidly, in confequence of the diminifhed area of the ciftern, when the alteration of velocity is confiderable, and a greater correction is required, than when the alteration is only trifling. It is neceffary that the pump fhould raife a conftant ftream of water into the ciftern, both in the afcent and defcent of its bucket: to do this, two pumps, acting alternately, may be ufed, or by a very fimple contrivance a fingle pump may be made to effect the fame; thus, upon the rod of the pump a cylinder of wood is fixed, which is of fuch a diameter, that its area is equal to half the area of the pump-barrel, and its length being equal to the length thereof, its content will be equal to one-half of the barrel: this is fixed on fuch a part of the rod, that it will, by the rifing and falling of the rod, be drawn up out of water as much as the rod and bucket moves: now, when the pump-bucket is drawn up, the rifing of the cylinder above the furface of the water increafes the capacity of the ciftern one-half as much as the quantity of water which is thus drawn up into it, and the efflux of water by the cock being juft equal to the other half, the furface will be ftationary; and when the bucket defcends, and no water is raifed, the cylinder going down into the water diminifhes the capacity of the ciftern a quantity equal to the quantity of water which will flow off in the fame time, and thus fupplies the wafte of water which flows off in the fame time. A regulator of this kind may, in many cafes, be formed from fome part of the machine, without any additional apparatus: thus, the cold water-pump of a fteam-engine will raife the neceffary water into a ciftern for the float to act in, and this float muft be connected with the arm of the fteam-valve. Alfo, in an engine for blowing a furnace, where it has a water-regulator (fee Blowing), the rife of the water in the external ciftern may regulate the motion of the engine, the whole machine being of the fame kind with the regulator we have defcribed.

A regulator would be applied with great advantage to a machine which is ufed in the *Cotton* Manufacture (fee that article), for drawing a piece of cotton cloth regularly and flowly over a red-hot cylinder of iron by two rollers, from one of which it is wound to the other: now, if the men who turn thefe ftop but for a moment the cloth is burnt through, but by a regulator it might be lifted off the hot iron the inftant the motion was fo far diminifhed as to endanger the firing of it.

The water-regulator is rendered more powerful by fufpending the ciftern from the end of a lever, like a fcale-beam, the oppofite end of which has a counterpoife fufficient to balance the weight of the ciftern when the water in it ftands at the intended height; but if the water increafes in the ciftern from the caufes above defcribed, the box will defcend, and the motion of the lever will act upon the machine to make the regulation the fame as the motion of the float: on the other hand, when the water in the ciftern diminifhes, the counterpoife will draw it up and give motion to the lever. The water from the pump is introduced to the ciftern by a fpout, and all the other parts have the fame conftruction as we have defcribed.

It is a defect of both the regulators we have above defcribed, that they do not operate upon the machine until the alteration of velocity has actually taken place, although they immediately correct it. It would be defirable to have others which would make the correction before the evil takes place: for inftance, in a wind-mill, which is more fubject to irregularity than any other machine, a large vane may be fufpended by a heavy pendulum, and oppofed to the wind; now the force of the latter, when blowing regularly, will caufe the pendulum to incline a certain quantity from the perpendicular; but if the wind increafes or diminifhes, it will incline more or lefs, and this motion may be communicated to the fhuttle which regulates the feed of corn, fo as to give more or lefs to the ftones in proportion to the power of the wind for grinding it, thus adapting the refiftance to the power; and if this fhould increafe beyond all bounds, the fame motion may be made to act upon the grip of the mill to check its acceleration effectually. In the fame manner a water-wheel may have a float placed in the dam or head to act upon the fhuttle whenever the furface thereof rifes or falls above or

below

below the intended level, fo as to apportion the fupply to the fall, and keep the velocity uniform.

There is another kind of regulator fometimes ufed in machines to caufe a fufficient refiftance to the motion to prevent acceleration, fuch as a crane or lowering machine, which is to let down a heavy weight, a coal winding machine, &c.; a very good one for thefe purpofes is a vertical axis with pendulums, like the governor, but having a broad vane to meet the air inftead of heavy balls, which indeed may be added alfo: this, when put in motion, will oppofe a very great refiftance to the acceleration, becaufe the centrifugal force caufing the vanes to recede from the centre, they muft defcribe a larger circle in the air in proportion to the velocity, or, by collapfing, they make but little refiftance when the velocity is fmall.

REGULO, a title given to the fons of the emperor of China.

REGULUS, Marcus Attilius, in *Biography*, a celebrated Roman general, was raifed to the confulfhip the firft time in the year 267 B. C., and, in conjunction with his colleague Libo, obtained the honour of a triumph on account of their fuccefs over the Salentines, from whom they took their capital Brundufium. During the firft Punic war the Romans elected Regulus conful, together with Lucius Manlius Vulfo, B.C. 256, and gave them orders to carry their arms into Africa. They failed with a very powerful fleet, and in their voyage encountered a fuperior Carthaginian force, under Hanno and Hamilcar, which they totally defeated. After refitting in Sicily, and taking frefh troops aboard, the confuls failed for the African coaft, where they took poffeffion of the town of Clupea. They next advanced towards Carthage, which city was thrown into the utmoft confternation by this unexpected invafion; and, after plundering the country almoft to its gates, they returned to Clupea loaded with booty of all kinds. Very foon after this, orders arrived from Rome for the return of Manlius, leaving Regulus with part of the fleet and army to conduct the war in Africa. Regulus afked for his recall upon the following plea: he was poffeffed of a farm of feven acres, from which his family derived their fubfiftence, and being informed that his fervants were carrying off his ftock, he begged that he might return to fave his family from ftarving. The plea was over-ruled, by an order that they fhould be maintained by the public during his abfence upon the fervice of his country. He again advanced towards Carthage, croffed the river Bagrada (in paffing which, according to the Roman hiftorians, he was encountered by a monftrous ferpent,) and laid fiege to a town not far from the metropolis. Hamilcar attempted to relieve the place, but Regulus met him and gave him a very fignal defeat. After this he took feveral towns, without any refiftance. A revolt of the Numidians reduced the Carthaginians to ftill greater diftrefs, fo that it appears the enemy fought for peace. The terms, however, offered by Regulus were fo unreafonable, that the fenate of Carthage could not for a moment liften to them, and refolved upon a vigorous profecution of hoftilities. During the interval of negociation a body of Greek mercenaries arrived at Carthage, commanded by Xantippus, a Spartan, by whom the Romans were completely defeated, with the lofs of 30,000 men, befides 15,000 taken prifoners, among whom was Regulus himfelf, whom the Carthaginians brought in triumph into that city, which, but a few hours before, he had not only infulted, but, in his own mind, devoted to deftruction. Hitherto, fays the hiftorian, Regulus had appeared only as a Roman commander, and not one of the moft confpicuous; the concluding fcenes of his life are thofe which entitle him to rank among the firft of Roman patriots. The Carthaginians behaved to their other prifoners humanely, but Regulus they treated with all the barbarity which they could devife; but, when the fortune of war appeared to turn againft them, they began to ufe him with more lenity, in order that they might engage him to endeavour to obtain an accommodation. At their defire he went with their ambaffadors to Rome, having firft taken an oath that he would return to his prifon, if the negociation fhould not fucceed. When he arrived at the gates of the city he refufed to enter, being, as he faid, a flave to the Carthaginians; and when his wife and children came out to meet him, he viewed them as ftrangers, and declined their careffes. The fenators affembled to give audience to the Carthaginian ambaffadors, preffed him to take his feat among them, but he refufed, till commanded by his mafters to accept it. When he was called on for his opinion, he fpoke ftrongly both againft granting the Carthaginians peace, and exchanging himfelf and the other Roman captives for the prifoners of importance whom they had taken from that nation. Though convinced by his arguments, the fenators were unwilling to fend back fo noble a citizen, and a fubterfuge was fuggefted to him by which he might be releafed from his oath, but he inftantly rejected the bafe fuggeftion, and declared his refolution to return to Carthage in the face of the cruel punifhment that he knew awaited him. Acting upon the idea that he was ftill a flave, he took no leave of his family, but, with an unmoved countenance, made his way in filence through the crowds of his admiring countrymen. The Carthaginians were told that their offers of peace were not only rejected at Rome, but chiefly fo through the means of Regulus, whom now they refolved to punifh in the fevereft manner poffible. For fome days he was expofed to the rays of a meridian fun, and afterwards confined in a barrel, whofe fides were every where filled with large iron fpikes, till he died in the greateft agonies. His fufferings were heard of at Rome, and the fenate permitted his widow to inflict whatever punifhment fhe pleafed on fome of the moft illuftrious captives of Carthage, and fhe took a fevere revenge, till at laft the fenate interpofed, and put a ftop to the barbarity of her punifhments. Regulus perifhed in the year B.C. 251. Univ. Hift.

Regulus, *Petty King*, in our *Ancient Cuftoms*, is a term frequently ufed, in the Saxon councils, for comes or count.

Hence *fub-regulus* was alfo ufed for a vice-comes or vifcount: though in many places the two feem ufed indifferently for the fame dignitary. Thus in the archives of the cathedral of Worcefter, Uthredus fometimes ftyles himfelf regulus, and fometimes fub-regulus, of the city of Worcefter.

But in other places we find a diftinction: "Offa, rex Merciorum; Uthredus, regulus; Aldredus, fub-regulus, &c."

Regulus, *Konig*, Germ., in *Chemiftry*, denotes, in its moft extenfive fenfe, a metal in the proper metallic ftate. The term is now little ufed, though the old chemifts chiefly employed it as a diftinctive appellation in thofe cafes where a metal and one of its ores happened to be called by the fame name. Thus, the grey fulphuret of antimony was not known by the name of antimony long before it was fufpected to contain a peculiar metal; when this difcovery took place, the metal was called regulus of antimony, in order to diftinguifh it from the ore from which it was procured. For the fame reafon, the metals arfenic and cobalt were denominated the reguli of arfenic and cobalt.

Regulus *of Antimony*. See Antimony.

Regulus, *Martial, of Antimony.* See Antimony.

Regulus *of Arsenic.* See Arsenic.

Regulus *of Cobalt.* See Cobalt.

Regulus, in *Astronomy*, is a star of the first magnitude, in the constellation Leo; called also, from its situation, *Cor Leonis*, or the *Lion's Heart*; by the Arabs, *Albabor*; and by the Chaldeans, *Kalbeleced*, or *Kalbeleceid*; from an opinion of its influencing the affairs of the heavens; as is observed by Theon. See Leo.

Regulus, in *Ornithology*, a species of *Falco*; which see. —Also, a species of *Motacilla*; which see.—See also Wren.

REGUSSE, in *Geography*, a town of France, in the department of the Var; 9 miles N.E. of Barjols.

REGYA, a river of Africa, which runs into the Mediterranean; 16 miles E. of Algiers.

REHABERE *facias seisinam*, quando vicecomes liberavit seisinam de majore parte, *quam deberet*, in *Law*, a writ judicial; of which there is another of the same name and nature. (Reg. Jud. 13, 51, 54.) It lay when the sheriff in the *Habere facias seisinam* had delivered more than he ought.

REHABILITATION, Rehabilitatio, in the *Civil* and *Canon Law*, an action by which a prince or pope, by dispensation or letters patent, restores a delinquent to the condition he was in before his delinquency. See Degradation.

The king alone can rehabilitate an officer, noted, condemned, and degraded; or a gentleman who has derogated from his rank.

The pope alone pretends to rehabilitate, *i. e.* to render capable of benefices and orders, such as had fallen into heresy or other irregularities.

In Romish countries, an ecclesiastic who assists at the execution of a sentence of death, is to be rehabilitated by an absolution, called *a sævis*.

By the *rehabilitation* of a convict in the Code Napoleon, or French criminal jurisprudence, is understood his restoration to all the rights and privileges which he had forfeited by being subjected to a painful or infamous punishment. He cannot demand it till five years have elapsed since the execution of his sentence, during the whole of which time he must have resided in the same *arrondissement*; or unless he has been domiciled during two complete years in the territory of the municipality to which the demand is addressed. It must also be supported by testimonials of his good conduct from the municipal authorities. The criminal court receives the demand, and pronounces on it at the end of three months: if their judgment be unfavourable, the application may be renewed at the end of five years, with the same advantage; but if the party rehabilitated into society should offend again, he becomes incapacitated for ever.

REHBURG, in *Geography*, a town of Westphalia, in the principality of Calenberg; 18 miles W.N.W. of Hanover.

REHEARING, in the *Court of Chancery*, is a process to which either party, that thinks himself aggrieved, may have recourse, before the execution of a final decree. Every petition for a rehearing must be signed by two counsel of character, certifying that they apprehend the cause is proper to be reheard. And upon the rehearing, all the evidence taken in the cause, whether read before or not, is now admitted to be read; because it is the decree of the chancellor himself, who only now sits to hear reasons why it should not be enrolled and perfected; at which time, all omissions of either evidence or argument may be supplied. But after the decree is once signed by the chancellor, and enrolled, it cannot be reheard or rectified, except by bill of review, or by appeal to the house of lords.

REHEARSAL, in *Music* and the *Drama*, an essay or experiment of some composition, which is made in private, previous to the representation or performance of it in public; to habituate the actors or performers, and make them more ready and perfect in their parts.

REHOBOTH, in *Geography*, a post-town of America, in Bristol county, Massachusetts, on a branch of Providence river, a few miles from Providence, in Rhode island, 40 miles southerly from Boston. It was called "Seconnet" by the Indians; incorporated in 1645, and contains 4866 inhabitants.

REHUT, a town of Hindoostan, in the circar of Gohud; 20 miles S.S.W. of Gwalior.

REI *Domesticæ Domesticus.* See Domesticus.

REICH, in *Geography*, a town of Austria; 7 miles N.W. of Schwanestadt.

REICHARDT, John Frederic, in *Biography*, chapelmaster to Frederic II. king of Prussia, at Berlin, was born at Königsberg, in Prussia, in 1751, and studied under the organist of the principal church. Richter taught him the harpsichord, and formed his taste. He likewise practised the violin, and was powerful upon that instrument, particularly in double stops. With these talents he travelled in 1771, distinguishing himself in Upper and Lower Saxony, Dresden, Leipsic, Brunswick, Hamburgh, and Berlin; where he was appointed by the king, in 1775, chapelmaster, in the station which Graun had formerly illustrated.

The first composition which he produced in his new office, was a prologue to Graun's opera of "Angelica e Medoro," which he set on occasion of a visit to the king of Prussia by the grand duke of Russia, in 1776; in which prologue he composed the famous air "Nell' orror d'Atra Foresta," for Mad. Mara.

In 1783 he went to Paris, and gave proofs of his abilities at the concert spirituel; and in 1784, he was present at the commemoration of Handel in London. He married the daughter of Francis Benda, born the same year as himself, an excellent singer.

REICHELIA, in *Botany*, Schreb. Gen. 200. (Sagonea; Aubl. Guian. t. 111. Juss. 134. Lamarck Illustr. t. 212.) Reduced by its author, on the suggestion of Swartz, to *Hydrolea*; Schreb. 826. There have been two botanists of the name of Reichel; but Schreber, most probably, had principally in view George Christian Reichel, professor of medicine at Leipsic, who published a dissertation on the Spiral Vessels of Plants, and died in 1771, at the age of 44.

REICHELSBERG, in *Geography*, a lordship of Germany, in the circle of Franconia, deriving its name from a mountain citadel, near the town of Aube, in the duchy of Wurzburg.

REICHELSBURG, a town of the duchy of Wurzburg; 20 miles S.E. of Wurzburg.

REICHELSDORF, a town of Bavaria, in the territory of Nuremberg; 7 miles S. of Nuremberg.

REICHELSHEIM, a town of the duchy of Wurzburg; 4 miles W. of Arnstein.—Also, a town of the principality of Nassau Weilburg, insulated in the bishopric of Fulda; 30 miles S. of Marburg.

REICHELSWAND, a town of Bavaria, in the territory of Nuremberg; 3 miles E. of Lauf.

REICHENAU, an island in the lake of Constance, about two miles long, and abounding with vines and other fruit

fruit trees, with a celebrated abbey, and the villages of Upper and Lower Zell.—Alfo, a town of Bohemia, in the circle of Chrudim; 9 miles W.N.W. of Politzka.—Alfo, a town of Auftria; 5 miles S.W. of Freyftadt.—Alfo, a town of Saxony, in the Vogtland, near Pawfa.—Alfo, a town of the Helvetian republic, at the union of the two branches of the Rhine; 6 miles S.W. of Coire.—Alfo, a town of Bohemia, in the circle of Bechin; 6 miles E. of Rofenberg.—Alfo, a town of Bohemia, called "New Reichenau," in the circle of Bechin; 8 miles E.S.E. of Pilgram.—Alfo, a town of Pruffia, in the province of Oberland; 8 miles S.E. of Ofterrod.—Alfo, a town of Pruffia, on the Offa; 22 miles E.N.E. of Culm.

REICHENBACH, a town of Saxony, in the Vogtland, containing about 700 houfes, two churches, and a Latin fchool. The inhabitants are chiefly clothiers, and dealers in cloth. Their method of dyeing is held in high eftimation, the moft beautiful fcarlet in the whole electorate being made at this place; 10 miles S.W. of Zwickau. N. lat. 50° 31′. E. long. 12° 16′.—Alfo, a town of Silefia, in the principality of Schweidnitz, containing two churches and an hofpital. The town has fome confiderable manufactures of linen, canvas, and fuftian; 9 miles N. of Schweidnitz. N. lat. 50° 35′. E. long. 16° 35′.—Alfo, a town of France, in the department of the Sarre; 8 miles S. of Lautereck.—Alfo, a town of Lufatia; 4 miles S.W. of Camenz.—Alfo, a town of Pruffia, in the province of Oberland; 7 miles S.S.W. of Holland.—Alfo, a town of Germany, in the county of Henneberg; 3 miles N. of Smalkalden.—Alfo, a town of Germany, in the principality of Culmbach; 12 miles E.N.E. of Neuftadt.—Alfo, a town of Germany, in the margraviate of Anfpach; 2 miles N.W. of Schwabach.

REICHENBERG, a mountain of Swabia; 6 miles N.W. of Huiffingen.—Alfo, a town of Bohemia, in the circle of Bolellaw. Twenty thoufand pieces of cloth are fuppofed to have been made in this town in one year; 25 miles N.N.E. of Jung-Buntzlau.—Alfo, a town of Pruffia, in the province of Ermeland; 3 miles S.W. of Heilfberg.—Alfo, a town and caftle of Weftphalia, in the county of Catzenelnbogen; 5 miles E. of St. Goar.

REICHENBURG, a town of the duchy of Stiria; 12 miles S.S.E. of Cilley.

REICHENECK, a town of the duchy of Stiria; 5 miles E.S.E. of Cilley.

REICHENFELS, a town with a caftle in Saxony, in the principality of Reuffen; 8 miles N.W. of Greitz.—Alfo, a town of the duchy of Carinthia; 24 miles N.E. of Clagenfurt.

REICHENHALL, a town of Bavaria, on the Sala, with a rich falt fpring, the water of which is partly boiled here, and partly, by means of a large wheel 36 feet in diameter, thrown up to the higher parts of a lofty houfe, and thence conveyed by means of leaden pipes to the diftance of 12 miles, over mountains, towards Traunftein, and there boiled, on account of the convenience of wood, and alfo of exportation. An aqueduct of fquared flints, two miles long and five feet broad, with an arched roof, was formed fome centuries ago, for conveying water to turn the wheels and other engines, and to carry off any fuperfluous falt water. This aqueduct, after running to a depth of 12 fathoms under the town, and from thence under the gardens and fields, at laft difcharges its water in a ftrong torrent. The current of the water is fo ftrong, that a boat with torches may fail from one end to the other in a quarter of an hour. In the aqueduct are five apertures in the form of towers, and through fome of thefe a perfon may fpeak from the ramparts of the town with thofe who fail upon the canal; 9 miles S.W. of Salzburg. N. lat. 47° 40′. E. long. 12° 50′.

REICHENSTAIN, a town of Auftria; 19 miles N.E. of Steyregg.

REICHENSTEIN, a town of Silefia, belonging to the principality of Brieg, but infulated in that of Munfterberg; 16 miles W. of Neiffe. N. lat. 50° 15′. E. long. 16° 40′.—Alfo, a town of France, in the department of the Roer; 21 miles S. of Juliers.

Reichenstein, *Unter*, a town of Bohemia, in the circle of Prachatitz; 3 miles W.S.W. of Berg Reichenftein.

REICHENTAL, a town of Auftria; 3 miles E. of Haderfdorf.

REICHENWALT, or Riecherswalde, a town of Pruffia, in Oberland; 4 miles N.W. of Liebftat.

REICHERSDORF, a town of Tranfylvania; 4 miles E. of Medies.

REICHMANSHAUSEN, a town of the duchy of Wurzburg; 10 miles E.N.E. of Schweinfurt.

REICHNAW, a town of Bohemia, in the circle of Konigingratz; 17 miles E.S.E. of Konigingratz.—Alfo, a town of Lufatia; 6 miles W. of Gorlitz.

REICHNICH, a town of the duchy of Stiria; 6 miles N.E. of Windifch Gratz.

REICHOLDSGRUN, a town of Germany, in the principality of Culmbach; 2 miles S. of Kirch Lamitz.

REICHSHOFEN, a town of France, in the department of the Lower Rhine; 9 miles N. of Haguenau.

REICHSTHABER, in *Commerce*. See Rix-dollar.

REICHTHAL, in *Geography*, a town of Silefia, in the principality of Breflau; 32 miles S. of Breflau. N. lat. 51° 9′. E. long. 17° 52′.

REID, Thomas, in *Biography*, an eminent divine and moralift, was born at Strachan, in Kincardinefhire, of which parifh his father was minifter, in the year 1710. The elements of learning he received at the parifh fchool of Kincardine, after which he was fent to a claffical fchool at Aberdeen; and fo rapid was his progrefs in his ftudies, that about the age of thirteen he was found fully qualified for the univerfity, and entered as a ftudent in Marifchal college. Here he diftinguifhed himfelf by his proficiency in the various branches of learning taught during the ufual courfe of four years, particularly in mathematics. At this period he probably took his degree of M.A., and afterwards commenced the ftudy of theology, and in due time was licenfed as a preacher. He was foon appointed librarian to the univerfity, and became intimately acquainted with Mr. John Stewart, the profeffor of mathematics. This connection ftrengthened and confirmed his predilection for mathematical ftudies. Occafionally he read lectures for his friend, in which he difcovered a happy faculty of making every thing intelligible to the ftudents, which he clearly apprehended himfelf. In 1736 Mr. Reid refigned his fituation of librarian, and accompanied Mr. Stewart on an excurfion into England, and became acquainted with many illuftrious characters in London, at Oxford, and at Cambridge. In the following year, Mr. Reid was prefented by the King's college of Aberdeen to the living of New Machar; but his entrance into the functions of his office was very unpropitious. His unwearied attention, however, to the duties of his office, the mildnefs and forbearance of his temper, and the active fpirit of his humanity, foon overcame all their prejudices; and not many years afterwards, when he was called to a different fituation, the fame perfons, who had taken a fhare in the outrages againft him, followed him, on his departure, with their prayers and tears.

tears. "We fought," faid fome of them, "againft Mr. Reid, when he came; and would have fought for him, when he went away."

The greater part of his refidence at New Machar was devoted to the moft intenfe ftudy; and by way of amufement, he had recourfe to gardening and botany, of which he was extremely fond, even in old age. In the year 1748 he publifhed a paper in the Tranfactions of the Royal Society of London, entitled "An Effay on Quantity, occafioned by reading a Treatife, in which fimple and compound Ratios are applied to Virtue and Merit." The treatife here referred to was Dr. Hutchefon's "Inquiry into the Origin of our Ideas of Beauty and Virtue."

The profeffors of King's college, Aberdeen, in the year 1752, appointed Dr. Reid to be profeffor of philofophy: the choice originated wholly from the high opinion they were led to entertain of his talents and erudition. It is not known what particular plan he purfued in the courfe of his lectures; but his department comprehended mathematics, and phyfics, logic, and ethics. Soon after his removal to this fituation, he projected, in conjunction with his friend, Dr. John Gregory, a literary fociety, which fubfifted many years, and which, it is believed, had confiderable effect in exciting and directing that fpirit of philofophical refearch, which has fince fo particularly diftinguifhed the north of Scotland. The writings of Reid, Gregory, Campbell, Beattie, and Gerard, evince the numerous advantages which the members derived from this inftitution, as they were in the habit of bringing fuch works as they intended for publication to the teft of friendly criticifm. Among thefe the moft original was that of our author, publifhed in 1764, entitled "An Inquiry into the Human Mind, on the Principles of Common Senfe;" intended to refute the philofophy of Locke and Hartley, by denying the connection which they fuppofed to fubfift between the feveral phenomena, powers, and operations of the mind; and accounting for the foundation of all human knowledge on a fyftem of inftinctive principles. About the time when this "Inquiry" made its appearance, the author received from the college of Aberdeen the degree of doctor of divinity; and by the univerfity of Glafgow he was invited to the profefforfhip of moral philofophy. On the duties attached to this office he entered in 1764; and he was enabled, by means of a handfome income, to concentrate all his attention to his favourite purfuits, which had hitherto been diftracted by the mifcellaneous nature of his academical engagements. The refearches of Dr. Reid concerning the human mind, were extended and methodized in a courfe, which employed five hours every week, during fix months in every year. The fubftance of thefe lectures was afterwards given to the world, in a more improved form, in the laft of his publications. In the year 1773 appeared, in the form of an appendix to the third volume of lord Kames' "Sketches of the Hiftory of Man," a brief account of Ariftotle's logic, with remarks by Dr. Reid. In the year 1781 Dr. Reid withdrew from his public labours, but he was not inactive: his fubfequent works afford proof of the affiduity with which he availed himfelf of his literary leifure. In 1785 he publifhed his "Effays on the Intellectual Powers of Man;" and in 1788, thofe "On the Active Powers." Thefe volumes complete the fyftem of philofophy, begun in his "Inquiry" many years before.

Notwithftanding his advanced age, Dr. Reid continued to profecute his ftudies with unabated ardour and activity. The modern improvements in chemiftry attracted his particular notice, and he applied himfelf with his accuftomed diligence to the ftudy of its theories and nomenclature. He amufed himfelf alfo, at times, in preparing for a philofophical fociety, of which he was a member, fhort effays on particular topics, which happened to intereft his curiofity, and on which he thought he might derive or afford ufeful hints in the courfe of friendly difcuffion. His laft effay appears to have been written in the 86th year of his age, and was read by the author to his affociates but a fhort time previoufly to his death. In the month of September 1796, he was feized with a violent diforder, with which he for fome time maintained a fevere ftruggle; but which, together with fome paralytic attacks, put an end to his ufeful life on the 7th of October, in the 87th year of his age. In point of bodily conftitution, few men have been more indebted to nature than Dr. Reid. His form was vigorous and athletic, and his countenance was ftrongly expreffive of deep and collected thought; but when brightened up by the face of a friend, what chiefly caught the attention was a look of good will and of kindnefs. The moft prominent features of his character were intrepid and inflexible rectitude, a pure and devoted attachment to truth, and an entire command over his paffions. In private life, no man ever maintained, more eminently or more uniformly, the dignity of philofophy; combining with the moft amiable modefty and gentlenefs, the nobleft fpirit of independence. As a public teacher, he was diftinguifhed by unwearied affiduity in inculcating principles, which he conceived to be of effential importance to human happinefs. In his elocution and mode of inftruction, there was nothing peculiarly attractive. Such, however, were the fimplicity and perfpicuity of his ftyle; fuch the gravity and authority of his character, that he was always liftened to with profound refpect, and, in his latter years, with a veneration, which age added to great wifdom always infpires. Stewart's Life of Reid.

REIDEN, in *Geography*, a town of Switzerland, in the canton of Lucerne; 18 miles N.N.W. of Lucerne.

REJECTIO, a word ufed by medical authors for the cafting any thing up preternaturally by the mouth, whether it be by vomiting or by fpitting.

REIFF, in *Geography*. See RIVA.

REIFFERSCHEID, a town of France, in the department of the Sarre, and chief place of a canton, in the diftrict of Prum. The place contains 311, and the canton 3542 inhabitants, in 45 communes. Alfo, a town of France, in the department of the Rhine and Mofelle, capital of a county in the archbifhopric of Cologne; 42 miles W. of Coblentz. N. lat. 50° 33′. E. long. 6° 27′.

REIFFLING, a town of the duchy of Stiria, on the river Enns; 28 miles N.W. of Pruck.

REIFFNITZ, a town of Middle Carniola; 4 miles N. W. of Gottfchee.

REIFTENBERG, a town of Auftria; 59 miles S.E. of Goritz.

REIGELSBERG, a lordfhip of the duchy of Wurzburg.

REIGNAC, a town of France, in the department of the Gironde; 9 miles N.E. of Blaye.

REIGNIER, a town of France, in the department of the Léman, and chief place of a canton, in the diftrict of Geneva. The place contains 1280, and the canton 9046 inhabitants, on a territory of 102½ kilometres, in 14 communes.

REIGNING WINDS, in *Meteorology*, are thofe winds which ufually prevail in any particular coaft or region, the knowledge of which is effentially neceffary to every pilot, who is charged with the navigation in thofe feas.

REIKENES, in *Geography*, a cape on the S. coaft of Iceland. N. lat. 63° 43′.

REIKEVIG, a sea-port town of Iceland, consisting of about 60 or 70 houses, standing in two rows of nearly equal length, at right angles to each other, the high street being encumbered with rock. Among the rocks, which on every side surround the town, are scattered wretched hovels, a little raised above the level of the ground. The adjacent country much resembles the summit of some of the highest mountains in Scotland, being composed of fragments of rocks, and presenting only a few patches of alpine vegetation. Almost all the houses of Reikevig are of Norwegian construction, and inhabited by Danes. The women of this town are principally employed in the operation of drying fish. On the little island of Akarve, near this town, are bred eider ducks in great numbers. About six miles to the south of Reikevig is an immense bed of lava, extending a length of 25 miles, and having its black and desolate surface broken into masses and fragments, which render it difficult and dangerous to traverse it, especially where quantities of the "trichostomum" conceal the hollow parts from view. The breadth of this remarkable current varies from two to ten miles; and its hideously shattered aspect is supposed to have resulted from the expansive force of elastic fluids which escaped during the cooling of the lava. Most of the produce of the Icelanders is brought to Reikevig; and the inhabitants of the interior of the country take back, in exchange for their tallow and skins, the dried heads of the cod-fish, and such fish as are injured by the rain and not fit for exportation. These form the principal article of their food, and are eaten raw, with the addition of butter, &c. Bishop Videlinus in this place has a library of 5 or 600 volumes. The author of the work now cited states the height of Hecla at about 5000 feet, and the population of Iceland at about 48,000 persons, who, from the rigour and instability of their climate, can never rely on their native produce even for the necessary articles of subsistence. The principal articles of export are dried fish, (especially cod of a superior quality,) mutton, lamb, beef, butter, tallow, train-oil, coarse woollen cloth, the skins of sheep, lambs and foxes, eider-down and feathers; and their chief importations are timber, fishing tackle, various implements of tin, tobacco, bread, spirituous liquors, salt, linen, &c. A large proportion of their food consists of fish, butter, and various preparations of milk. Hooker's Journal of a Tour in Iceland in 1809.

REILLANE, a town of France, in the department of the Lower Alps; 7 miles S. of Forcalquier.

REIMBURSEMENT, in *Commerce*, the act of repaying or returning what monies a person had received, by way of advance, &c. or what another had disbursed or paid for him. A person who gives a bill of exchange in payment, is to reimburse it, if it come to be protested, for want of being accepted or paid.

REIMBURSING is also used for paying the price a commodity costs its owner.

REIMS, or RHEIMS, in *Geography*, one of the most ancient and celebrated cities of France, and principal place of a district, in the department of the Marne, seated on the Vesle. Before the revolution this city was the see of an archbishop, who was the first duke and peer of France, and always crowned the king. In this place was the abbey of the Benedictines of St. Remy, the noblest of that order in the kingdom of France; and on the altar of its church, under which St. Remigius was buried, was kept the holy vial, which, as tradition reports, was, in the year 496, at the baptism of Clovis by bishop Remigius, brought from heaven by a dove in deference to the prayer of that saint; the crowd obstructing his passage to the font with the usual oil. The university of Reims was founded in 1547, and in the following year authorised by the parliament of Paris. This city contains 30,295 inhabitants, in the three parts into which it is divided, and it has three corresponding cantons, the first containing 12,140, the second 10,107, and the third 10,874, in three, four, and five communes respectively, on a territory of 117½ kiliometres. Rheims carries on a considerable trade in wine, woollen and silk stuffs, and gingerbread. It has several remains of Roman antiquities, particularly the three gates of the city, which still bear the names of as many Pagan deities, *viz.* the Sun, Mars, and Ceres. It was taken by the English in the reign of Henry V. N. lat. 49° 15′. E. long. 4° 6′.

REIN, a town of the duchy of Stiria; 9 miles N.W. of Gratz.—Also, a town of the same duchy, on the river Save; 20 miles E. of Cilley.

REIN-*Deer*, in *Zoology*. See CERVUS *Tarandus*.

REINDORFF, in *Geography*, a town of Bavaria; 4 miles S.S.W. of Bamberg.

REINECCIUS, REINIER, in *Biography*, a learned German, who flourished in the 16th century, was a disciple of Melancthon, and taught the belles lettres in the universities of Frankfort and Helmstadt till his death, in 1595. He is known to the learned world by several works on history and genealogy, in which he was profoundly versed. His chief publications are, "Syntagma de Familiis Monarchiarum trium priorum," 1574; "Familiæ Regum Judæorum;" "Chronicon Hierosolymitanum;" "Historia Orientalis;" "Historia Julia," three vols. folio; "Methodus Legendi Historiam."

REINECK, in *Geography*, a town of France, in the department of the Rhine and Moselle, late capital of a burgravate, deriving its name from it, and situated between the duchy of Juliers and electorate of Cologne, on the borders of the Rhine; 14 miles N.N.W. of Coblentz.

REINEN. See RHEINE.

REINERTZ, a town of Silesia, in the comté of Glatz, on the borders of Bohemia; famous for its manufactures of beautiful cloth and plush, and excellent paper, equal to the best in Holland; 11 miles W. of Glatz. N. lat. 50° 14′. E. long. 16° 10′.

REINFELDT, a town of Prussia, in the province of Pomerelia; 12 miles S.W. of Dantzic.

REINFORCE, in *Gunnery*, is that part of a gun next to the breech, which is made stronger, to resist the force of the powder. There are generally two reinforces in each piece, called the first and second reinforce: the second is somewhat smaller than the first, upon the supposition that when the powder is inflamed and occupies a greater space, its force is diminished, which is very absurd. See CANNON.

REINFORCE *Rings* of a cannon, are flat mouldings like iron hoops, placed at the breech-end of the first and second reinforce, projecting beyond the rest of the metal about one-fourth of an inch. See CANNON.

REINFORCEMENT, in *War*, a supply, or new provision of men, arms, ammunition, &c.

REINGUS, in *Geography*, a town of Austria; 12 miles N.N.W. of Waidhoven.

REINHARTSBRUNN, a town of Germany, in the principality of Gotha; 10 miles S.S.W. of Gotha.

REINHARTZ, a town of Saxony; two miles W. of Schmiedelberg.

REINHEIM, a town of the principality of Hesse Darmstadt; 5 miles S.E. of Darmstadt.

REINHOLD, ERASMUS, in *Biography*, an eminent German mathematician, was born at Salfeldt, in Thuringia, a province in Upper Saxony, in the year 1511. He was educated

educated at the univerſity of Wittemberg, where his genius chiefly inclined him to the ſtudy of the mathematics, which he cultivated with great ſucceſs. He afterwards became a profeſſor of thoſe ſciences in the ſame univerſity, and acquired very high reputation, not only by his lectures, but by the learned and uſeful writings which he communicated to the public. Of theſe, which are very numerous, we may mention "Theoriæ Novæ Planetarum G. Purbachii," augmented and illuſtrated with diagrams and ſcholia. "Ptolemy's Almageſt, with a Latin Verſion, and Scholia." In 1551 he publiſhed "Prutenicæ Tabulæ Cœleſtium Motuum," which were ſeveral times reprinted. In carrying on this work, which coſt ſeven years' labour, he was encouraged by the munificence of Albert, duke of Pruſſia. They were conſtructed by him from a compariſon of the obſervations of Copernicus with thoſe of Ptolemy and Hipparchus, and he has fully explained the uſe of them in a great number of precepts and canons, forming a complete introduction to practical aſtronomy. Reinhold alſo made many aſtronomical obſervations, but he never had any better inſtrument than a wooden quadrant. The reſult of theſe obſervations were ſhewn to Tycho Brahé after the death of Reinhold, who expreſſed his ſurprize that ſo great and meritorious a cultivator of aſtronomical ſcience was not furniſhed with better inſtruments. Reinhold died in 1553, when only in the 42d year of his age, pronouncing the following verſe a ſhort time before he expired.

"Vixi, et quem dederas curſum mihi, Chriſte, peregi."

He had a ſon of the ſame name, eminent as a mathematician and phyſician, who publiſhed a ſmall work in the German language "On Subterranean Geometry;" alſo a tract concerning the new ſtar which appeared in Caſſiopeia in 1572.

REINISCHDORF, in *Geography*, a town of Sileſia, in the principality of Neiſſe; 5 miles N. of Neiſſe.

REINS, in *Anatomy*, the kidneys. See KIDNEY and RENES.

The word, according to Varro, is formed from the Greek, ῥεῖν, *quaſi rivi obſceni humoris ab iis oriantur.*—The Greeks call the rein νεφρος, from the verb νεφειν, *to rain, ſnow*, &c.

In the manege they ſay, a horſe ſhould have *double* reins; that is, he ſhould have them a little more elevated on each ſide of the back-bone, than upon it; ſo that, paſſing your hand along it, you find it large, well-furniſhed, and double, by the hollow that goes all along the back-bone. The back ſhould be firm and not hollow, or bending from the withers to the croup, but ſtraight.

REINS, of a bridle, alſo denote two ſtraps of leather meeting in the bridle-hand of the horſeman, in order to make the bit bear, and keep the horſe under ſubjection. See BRIDLE.

It is alſo a name given by the duke of Newcaſtle to two ſtraps or ropes of a caveſſon, which he ordered to be made faſt to the girths, or the pommel of the ſaddle, with intent that the rider ſhould pull them with his hand, in order to bend and ſupple the neck of the horſe.

REIN, *Falſe*, is a lath of leather, paſſed ſometimes through the banquet, to bend the horſe's neck, which is diſapproved of by the duke of Newcaſtle, becauſe it ſlacks the curb, and makes the bit no more than a trench that has no curb.

REINS, in *Rural Economy*, the long thongs or ſtrips of leather, or other materials, by which horſes or other animals are directed in carriages or teams. Theſe reins are much uſed in ſome counties, as Norfolk and Suffolk, in directing the plough-teams, in order to ſave the expence of another perſon, the ploughman directing them in this way himſelf, the driver being by this means diſpenſed with.

REINS, *Check*, a term ſignifying the ſame thing as a ſort of rein, and which is made uſe of in particular diſtricts, in checking and directing the animals.

REINS, *Whip*, a term uſed to ſignify a ſort of hempen rein, employed for directing the team in ploughing in ſome diſtricts, ſo called in conſequence of being uſed inſtead of whips.

REINS *of a Vault*. See VAULT.

REINSBERG, or RHINSBERG, in *Geography*, a town of Brandenburg, in the Middle Mark; 10 miles N.N.E. of New Ruppin. N. lat. 53° 4′. E. long. 12° 58′.

REINSCHNICK, DER, a mountain of Stiria; 12 miles S.E. of Landſperg.

REINSDORF, a town of Saxony, in the circle of Erzgebirg; two miles E.S.E. of Zwickau.

REINSPURG, a town of Bavaria, in the territory of Rothenburg; ſix miles S.S.W. of Rothenburg.

REINSTATING, the reſtoring of a perſon or thing to its former ſtate or condition, from whence it had been diſturbed or diſplaced. See REHABILITATION.

REINSTEIN, in *Geography*. See REGENSTEIN.

REINSURANCE, or RE-ASSURANCE, in *Commerce*, a contract by which a firſt inſurer relieves himſelf from the riſks which he has undertaken, and devolves them upon other under-writers, called re-inſurers, or re-aſſurers. When a policy of inſurance has been once ſigned, the under-writers are bound by the terms of it; nor can they be releaſed from their contract without the conſent of the inſured. But if an under-writer repent of what he has done; if he be afraid to encounter the riſk which he has engaged to run; or if he find that he has incautiouſly engaged himſelf to a greater amount than he may be able to diſcharge, he may ſhift it, or part of it, from himſelf to other inſurers, by cauſing a re-inſurance to be made on the ſame riſk, upon the beſt terms in his power, and the new inſurers will be reſponſible to him in caſe of loſs, to the amount of the re-inſurance. But in ſuch caſe, the new inſurers are reſponſible to the original under-writer only, and not to the original inſured, who can have no remedy againſt him, in caſe of loſs, even though the original inſurer become inſolvent; becauſe there is no privity of contract between the original inſured and the re-inſurer. If, therefore, the original inſurer fail, ſo that the original inſured receive only a dividend, however ſmall, the re-inſurer can gain nothing by this, but muſt pay the full amount of the loſs to the original inſurer. Such is the law on this ſubject, in moſt of the commercial ſtates of Europe. But in this country it was found, about the time when the ſtatute 19 Geo. II. c. 17. was made, that this mode of inſurance, though perfectly reaſonable, when confined to its proper object, had been perverted from its original uſe, and was employed as a mode of ſpeculating in the riſe and fall of premiums; and the legiſlature foreſeeing that it might be uſed as a colour for wager policies, and a means of evading the proviſions of that act, declares (ſect. 4.) "that it ſhall not be lawful to make re-inſurance, unleſs the inſurer ſhall be inſolvent, become bankrupt, or die; in either of which caſes, ſuch inſurer, his executors, adminiſtrators or aſſigns, may make re-inſurance to the amount of the ſum before by him inſured; provided it be expreſſed in the policy to be a re-inſurance." This clauſe, having no words to confine its operation to ſhips belonging to Britiſh ſubjects, like the firſt clauſe of the act reſtraining inſurances, *intereſt or no intereſt*, extends to re-inſurances made in England in foreign ſhips, even when they are inſured abroad. This has been ſo determined; though it is obſervable that the following caſe, in which

which that queſtion was made, was not the ſpecies of re-inſurance above deſcribed, and to which only the ſtatute refers, but a *ſecond inſurance,* effected on account of the *original inſured.*

That was the caſe of an inſurance made in London, on a French veſſel, which had before been inſured at Marſeilles for the ſame ſum, by an inſurer there, who, at the time of ſubſcribing the ſecond policy, was living and ſolvent, and who, in fact, afterwards paid the ſum inſured by him. Upon this caſe the court determined that the latter policy was void by the words of the act; for though the firſt clauſe of the act which prohibits inſurances, 'intereſt or no intereſt,' is confined to inſurances on Britiſh ſhips, yet the fourth ſection being general, and without any ſuch reſtrictive clauſe, every re-inſurance in this country, either by Britiſh ſubjects, or foreigners, on Britiſh or foreign ſhips, is declared void by the ſtatute, unleſs the firſt inſurer be inſolvent, become bankrupt, or die.

There are two other kinds of re-inſurance; the one where the inſured inſures the ſolvency of the inſurers; the other, where he makes a new inſurance, in conſequence of the inſolvency of an inſurer during the continuance of the riſk.

The inſurance of the ſolvency of an inſurer is permitted and practiſed in ſome foreign countries; but it ſeems never to have been in uſe among us; not, perhaps, as has been ſuppoſed, becauſe the ſolvency of an under-writer is not an inſurable intereſt, or that ſuch an inſurance would be deemed a wager; but, more probably, becauſe the inſolvency of an inſurer ſeldom happens in England; beſides, a *double inſurance* would better anſwer the end propoſed.

If France, if an inſurer fail during the continuance of the riſk, the inſured may inſiſt on the diſſolution of the contract, unleſs the creditors of the inſolvent inſurer, in order to entitle themſelves to receive the premium, (which is rarely paid in that country till after the riſk is ended,) will give ſecurity for the payment of the ſum inſured, in caſe of loſs. At Marſeilles, (for in France different practices prevail in different provinces,) the inſured, in ſuch caſe, ſues the inſolvent inſurer, till he obtains a ſentence, authorizing him to re-inſure at the expence of the inſolvent, which he may deduct from the ſtipulated premium, if it be not paid, and if this be inſufficient, then out of the effects of the inſolvent.

Double inſurance is where the inſured makes two inſurances on the ſame riſk, and the ſame intereſt; and it differs from a re-inſurance in this, that it is made by the *inſured,* in order that he may be entitled to receive a double ſatisfaction, in caſe of loſs; whereas, a re-inſurance is made by a former inſurer, his executors or aſſigns, to protect himſelf and his eſtate from a riſk to which they were liable by the firſt inſurance. A re-inſurance, except in the caſes permitted by the ſtat. 19 Geo. II. c. 37. § 4, is abſolutely void; but a double inſurance, though it be made with a view to a double ſatisfaction in caſe of loſs, and is therefore in the nature of a wager, is not void by the law of England. The two policies are conſidered as making but *one inſurance.* They are good to the extent of the value of the effects put in riſk: but the inſured ſhall not be permitted to recover a double ſatisfaction. He may ſue the under-writers on both the policies, but he can only recover the real amount of his loſs, to which all the under-writers ſhall contribute in proportion to their ſeveral ſubſcriptions. And therefore, if he ſhould content himſelf with ſuing only on one of the policies, the under-writers on that policy may recover a rateable contribution from thoſe on the other.

In conſequence of the determination of lord Mansfield, in 1763, it has been agreed to be the courſe of practice, that, upon a double inſurance, though the inſured is not entitled to two ſatisfactions, yet, that in an action upon the firſt policy, he may recover the whole ſum inſured, and may leave the defendants therein to recover a rateable ſatisfaction from the other inſurers. Formerly, in the caſe of an *over-inſurance,* that is, where, in a ſingle policy, the ſums ſubſcribed amount to much more than the value of the effects inſured, the firſt under-writers on the policy were holden to be anſwerable to the extent of the loſs, and the ſubſequent ones diſcharged. Although only a ſingle ſatisfaction can be recovered on a double inſurance by the ſame perſon, yet different perſons may inſure the ſame thing, and each recover the full value of the thing inſured. To enable the defendant, in an action on a policy, to diſcover whether there be a double inſurance, he may, by the authority of the ſtatute 19 Geo. II. c. 37. § 6, call upon the plaintiff to declare in writing, what ſums he has inſured in the whole, and how much he has borrowed on bottomry or reſpondentia. Marſhal's Treatiſe on the Law of Inſurance, vol. i. ch. 4. § 4.

REINTAL, in *Geography,* a town of Auſtria; four miles E.S.E. of Feldſberg.

REINTEGRATION. See Redintegration.

REJOICING Fire, in *Military Affairs,* is uſed on obtaining a victory, or in celebrating ſome public feſtival: of this there are two ſorts, *viz.* one by a volley, and the other by a running fire, from the right to the left of the battalion or line.

REJOINDER, in *Law,* the defendant's anſwer to the plaintiff's replication.

The order of the court of chancery is thus; firſt, the defendant puts in an anſwer or plea to the plaintiff's bill, which is ſometimes alſo called an *exception;* the plaintiff's anſwer to this is called a *replication;* and the defendant's anſwer to that, a *rejoinder.*

The plaintiff may anſwer the rejoinder by a *ſur-rejoinder,* upon which the defendant may *rebut;* and the plaintiff may anſwer him by a *ſur-rebutter;* which pleas, replications, rejoinders, ſur-rejoinders, rebutters, and ſur-rebutters, anſwer to the *exceptio, duplicatio, triplicatio,* and *quadruplicatio* of the Roman laws. See Pleading.

REJOINTING, or Rejoynting, in *Architecture,* the filling up of joints of the ſtones in old buildings, &c. when worn hollow by the courſe of time, or by weather.

Rejointing is to be performed with the beſt mortar, as that of lime and cement; ſometimes alſo with plaiſter; as in the joints of vaults, &c.

REIPOLTZHEIM, in *Geography,* a town of the duchy of Wurzburg; three miles N.E. of Schwarzbach.

REIPOLTZKIRCHEN, a caſtle of France, in the department of Mont Tonnerre, which gave name to a lordſhip, ſituated in the Hunſruck; five miles E. of Lautereck.

REIS, Re, or *Res,* in *Commerce.* See Rees.

REISBACH, in *Geography,* a town of Lower Bavaria, in the Vils; 35 miles W. of Paſſau.

REISCH, a town of Moravia, in the circle of Iglau; 18 miles S. of Iglau.

REISCHSTADT, a town of Bohemia, in the circle of Boleſlau; two miles N.W. of Nimes.

REIS-EFFENDI, in the *Turkiſh Empire,* one of the ten members of the *divan,* (which ſee,) or council of the grand viſir, of which the viſir and mufti are the preſidents. The reis-effendi is a kind of ſecretary of ſtate, high chancellor of the empire, and miniſter for foreign affairs. He ſigns all the orders of the Porte, which do not directly concern the finances and the military operations; he treats with all the European miniſters who are at Conſtantinople: in a word, every thing that concerns the foreign powers, and every

every thing that relates to the interior adminiſtration, paſs through the channel of the reis-effendi; but he does nothing without communicating it to the grand viſir, and taking his orders. In this council there are alſo two *ex-reis-effendi.*

REISENBERG, in *Geography*, a town of Auſtria, on the Reiſenpach river; 12 miles S.E. of Vienna.

REISENBURG, a town of Pruſſia, in the province of Oberland, built in the year 1169, and anciently the reſidence of the biſhops of Pomerania. The chief ſubſiſtence of the inhabitants is derived from brewing and agriculture; near it is an ancient caſtle; 78 miles S.W. of Konigſberg.

REISENGEBERG, a town of Bohemia, in the circle of Konigingratz. N. lat. 50° 40′. E. long. 15° 30′.

REISENPACH, a river of Auſtria, which runs into the Danube; 12 miles below Vienna.

REISHOFFEN, a town of France, in the department of the Lower Rhine; 21 miles N. of Straſburg.

REISJARVI, a town of Sweden, in the government of Ulea; 47 miles E. of Gamla Karleby.

REISKE, John James, in *Biography*, a learned philologiſt, born in 1716, at Zorlis, in Miſnia, was the ſon of a tanner in that place. He was, at the age of twelve, ſent to the orphan-ſchool at Halle, where he made a rapid progreſs in the learning of the place. In 1733 he entered at the univerſity of Leipſic, and being deſtined for the theological profeſſion, he ſpent five years chiefly in the ſtudy of rabbinical writings, and in the ſtudy of the Arabic language. To the latter he became ſo ardently attached, and his paſſion for Arabic books was ſo ſtrong, that he almoſt deprived himſelf of neceſſaries to purchaſe them. He went to Holland with the view of improving himſelf in his favourite language, and while there, he ranſacked all the Oriental treaſures of the library at Leyden, while, for his ſubſiſtence, he was obliged to become a corrector of the preſs. He paſſed his time in a ſtate of indigence that brought upon him hypochondriac affections, the effects of which never left him. During his reſidence at Leyden, he was preſented with a gratuitous degree in phyſic, but he never intended to avail himſelf of it in the way of practice: "Poverty," ſays his biographer, "was his perpetual companion, and his ſcanty reſources were derived from correcting the preſs, tranſlating, and performing other taſks for bookſellers." Many learned pieces in Oriental and Greek literature occaſionally proceeded from his pen, which made him well known in the learned world: and ſeveral of the works edited by him are held in very high eſtimation. He was at laſt nominated rector of the college of St. Nicholas, in Leipſic, a ſituation which enabled him to purſue his literary labours more according to his inclination. At the age of forty-eight he married Erneſtine Muller, a young woman of twenty-five, who, under his inſtructions, acquired ſo much knowledge of the Greek and Latin, and ſome modern languages, that ſhe became extremely uſeful to her huſband in his editorial employments. He died at the age of fifty-eight, in the year 1774. Of the moſt valuable works of Reiſke, are "Diſſertatio de Principibus Muhamedanis qui aut ab Eruditione aut ab Amore Literarum inclaruerunt;" "Animadverſiones in Sophoclem;" "Animadverſiones in Auctores Græcos;" "Oratorum Græcorum," 8 vols.; "Plutarchi Opera omnia;" "Maximi Tyrii Diſſert.;" "Apparatus Critici ad Demoſthenem," 3 vols. And after his death were publiſhed his "Conjecturæ in Jobum et Proverbia Salomonis, cum Oratione de Studio Arabiæ Linguæ." The "Acta Eruditorum" were much indebted to the pen of Reiſke.

REISNITZ, in *Geography*, a town of the duchy of Carniola; four miles N.W. of Gottſchee.

REISSENDORF, a town of Sileſia, in the principality of Neiſſe; four miles N. of Patſhkau.

REISTEN, a town of the duchy of Wurzburg; ſix miles N.N.E. of Arnſtein.

REISTERSTOWN, a poſt-town of America, in Baltimore county, Maryland; ten miles S.E. of Weſtminſter.

REITERATED Grafting. See Grafting.

REITERATING, in *Printing*. See Printing.

REITERATION, the act of repeating a thing, or doing it a ſecond time.

The church does not allow of the reiteration of baptiſm. St. Gregory obſerves, that it is no reiteration when there are wanting proofs of the thing's having been regularly done before.

REITLENGIN, in *Geography*. See Reutlengin.

REITTERECK, a town of Stiria; ſeven miles E. of Voitſburg.

REITTERS, an ancient title given the German cavalry. The word is originally High Dutch, and ſignifies a horſeman, cavalier, or even knight.

REITZ, in *Geography*, a town of Portugal, in the province of Beira; three miles N. of Viſeu.

REKEK, a ſmall iſland in the Eaſt Indian ſea. S. lat. 1° 33′. E. long. 128° 40′.

RELAIS, in *Fortification*, a French term, the ſame with *berme*.

RELAND, Adrian, in *Biography*, an eminent orientaliſt and polite ſcholar, was born in the year 1676, at a village in North Holland. He was educated at Amſterdam, and made ſuch progreſs in learning, that, having gone through the uſual claſſical courſe when he was only eleven years old, he employed the next three years in making himſelf acquainted with the Hebrew, Syriac, Chaldee, and Arabic languages. At the age of fourteen he was ſent to the univerſity at Utrecht, and in three years was admitted to the degree of doctor in philoſophy, and on this occaſion he ſuſtained a theſis "De Libertate Philoſophandi." After a reſidence of ſix years at Utrecht he removed to Leyden, and was in a ſhort time choſen by the earl of Portland as preceptor to his ſon. At the age of twenty-four, the univerſity of Harderwyk nominated him to the chair of philoſophy, but he did not remain long in that ſituation, for the univerſity of Utrecht, on the recommendation of king William, invited him to the profeſſorſhip of the Oriental languages and Jewiſh antiquities, which he accepted, and occupied with high reputation during the remainder of his life. He died at the age of 43, in the year 1719. Few writers have met with more general applauſe than Reland. His principal works, which are all extremely valuable, are; 1. "Paleſtina Monumentis veteribus illuſtrata," 2 vols. 4to. 2. "Diſſertationes de nummis veterum Hebræorum." 3. "Antiquitates ſacræ veterum Hebæorum." 4. "Introductio ad Grammaticam Hebræam." 5. "De Spoliis Templi Hieroſolymitani in Arcu Titiano Romæ conſpicuis." 6. "De Religione Muhamedica." Beſides theſe he publiſhed many other things. In private life he was diſtinguiſhed by his modeſty, humanity, and learning, and carried on a correſpondence with the moſt eminent ſcholars of his time. Moreri.

RELAPSE, in *Medicine*, the recurrence of a diſeaſe during the period of convaleſcence.

Relapſes of all diſeaſes, whether acute or chronic, are deemed more dangerous than the original attack; becauſe the conſtitution, being already debilitated and reduced by the previous illneſs, is leſs capable of reſiſting the farther ravages of diſeaſe. This may be ſaid to be true of all acute diſeaſes,

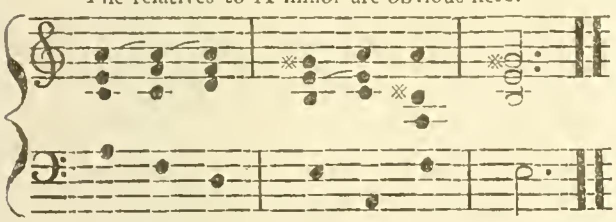
R E L

diſeaſes, ſuch as fevers, dyſenteries, inflammations of the lungs, liver, &c. Nevertheleſs, relapſes of theſe diſorders are not always fatal; becauſe, as the weaker conſtitution is leſs capable of being excited to violent action, ſo theſe ſecond attacks are ſometimes milder, and more eaſily influenced by remedies. Relapſes of chronic diſeaſes, ſuch as dropſies or jaundice, are more unfavourable; becauſe their recurrence implies that the internal diſeaſe, from which they originate, is not removed, but has only been temporarily alleviated.

RELATIO, Lat., *Relation*, Engl., in *Muſic*. Relative ſounds are in general ſuch as belong to two or more chords, as in the key of C. The chords of A, F, G, and E, are relative chords; as E, the 5th of A, is 3d of C: in the chord of F, C is the 5th; in the chords of G and E, each of thoſe ſounds is a part of the chord of C.

C major.

The relatives to A minor are obvious here.



In the modulation by riſing and falling a 3d in the baſe, two relative notes are in common with each chord. The moſt agreeable relation of a minor key to a major, is in the modulation from a minor key to the 3d above: as from A to C, or D to F; the ſcales of both keys being the ſame in deſcending. But falling a 3d in the baſe from a minor 3d to a major, as from A to F, or from D to B♭, is ſtill more pleaſing.

Falſe relation is C✕ againſt C♮, or G✕ in the chord of C♮. But even theſe falſe relations are allowed now, as *paſſing-notes* of taſte, though not in the body of the harmony.

RELATION, Relatio, in *Philoſophy*, the mutual reſpect of two things; or what each is with regard to the other.

The word is formed *a referendo:* relation conſiſting in this, that one thing is referred to another: whence it is alſo called *reſpect*, *habitude*, and *compariſon*.

The idea of relation we acquire, when the mind ſo conſiders any thing, that it doth, as it were, bring it to, and ſet it by, another, and carry its view from the one to the other. Hence the denominations given to things intimating this reſpect, are called *relatives;* and the things ſo brought together, are ſaid to be *related*.

Thus, when I call Caius *huſband*, or this wall *whiter*, I intimate ſome other perſon or thing in both caſes, with which I compare *him* or *it*. Hence the wall is called by the ſchoolmen the *ſubject;* the thing it exceeds in whiteneſs, the *term;* and the whiteneſs, the *foundation* of the relation.

Relation may be conſidered two ways; either on the part of the mind referring one thing to another; in which ſenſe relation is only a mode or affection of the mind, by which we make ſuch compariſon; or on the part of the things referred, which being no other than ideas, relation, in this ſenſe, is only a new idea reſulting or ariſing in the mind upon conſidering of two other ideas. So that relation, take it as you will, is only in the mind, and has nothing to do with the things themſelves.

Any of our ideas, Mr. Locke obſerves, may be the foundation of relation. Though where languages have failed to give correlative names, the relation is not eaſily taken notice of; as in concubine, which is a relative name, as well as wife.

There is, in effect, no idea but is capable of an infinite number of relations: thus, one ſingle man may at once ſuſtain the relations of father, brother, ſon, huſband, friend, ſubject, general, European, Engliſhman, iſlander, maſter, ſervant, bigger, leſs, &c. to an almoſt infinite number; he being capable of as many relations as there can be occaſions of comparing him to other things in any manner of agreement or diſagreement, or any reſpect whatſoever.

The ideas of relations are much clearer and more diſtinct than thoſe of the things related; becauſe the knowledge of one ſimple idea is oftentimes ſufficient to give the notion of a relation; but, to the knowing of any ſubſtantial being, an accurate connection of ſeveral ideas is neceſſary.

The perception we have of the relations between the various ideas in which the mind acquieſces, makes what we call *judgment*. Thus, when I judge that twice 2 make 4, or do not make 5, I only perceive the equality between twice 2 and 4, and the inequality between twice 2 and 5.

The perception we have of the relations between the relations of various things, conſtitutes what we call *reaſoning*. Thus, when from this that 4 is a ſmaller number than 6, and that twice 2 is equal to 4, I gather, that twice 2 is a leſs number than 6; I only perceive together the relation of the numbers twice 2 and 4, and the relation of 4 and 6.

The ideas of cauſe and effect, we get from our obſervation of the viciſſitude of things, while we perceive ſome qualities or ſubſtances begin to exiſt, and that they receive their exiſtence from the due application and operation of other beings. That which produceth, is the cauſe; that which is produced, is the effect.

Thus, fluidity in wax is the effect of a certain degree of heat, which we obſerve to be conſtantly produced by the application of ſuch heat.

The denominations of things taken from time are, for the moſt part, only relations. Thus, when it is ſaid, that queen Elizabeth lived ſixty-nine, and reigned forty-five years, no more is meant, than that the duration of her exiſtence is equal to ſixty-nine, and of her government to forty-five, annual revolutions of the ſun; and ſo are all words anſwering to how long.

Young and old, and other words of time, that are thought to ſtand for poſitive ideas, are indeed relative, and intimate a relation to a certain length of duration, of which we have the ideas in our minds. Thus, we call a man young or old, that had lived little or much of that time which men uſually attain to: and thus a man is called young at twenty, but a horſe old at the ſame period.

There are other ideas that are truly relative, which we ſignify by names that are thought poſitive and abſolute; ſuch as great and little, ſtrong and weak. The things thus deno-

minated

minated are referred to fome ftandards, with which we compare them: thus, we call an apple *great*, which is bigger than the ordinary fort of thofe we have been ufed to; and a man *weak*, that has not fo much ftrength or power to move as men ufually have, or as others of his own fize have.

Authors give various divifions of relations. The fchool philofophers commonly divide them into thofe of *origination*, under which are comprehended the relations of caufe and effect; thofe of *negation*, which are between oppofite things; and thofe of *affirmation*, which are relations of agreement between whole and part, the fign and thing fignified, the adjunct and fubject. This divifion is founded upon this, that the mind can only compare things three ways; *viz.* by inferring, denying, and affirming.

Others divide relations into thofe of *origination;* thofe of *agreement*, *e. gr.* fimilitude, parity, &c.; thofe of *diverfity;* and thofe of *orders*, as priority, pofteriority, &c.

Others divide them into *predicamental* and *tranfcendental*. Under the firft come thofe relations between things that belong to the fame predicament, *e. gr.* between father and fon. To the latter belong thofe which are more general than the predicaments, or are of different predicaments; as the relations of fubftance and accident; of caufe and effect; and of Creator and creature.

Mr. Locke gives us a diftribution of relations on a different principle. All fimple ideas, he obferves, in which are parts or degrees, afford an occafion of comparing the fubjects in which they are to one another, in refpect of thofe fimple ideas; as whiter, fweeter, more, lefs, &c. Thefe, depending on the equality and excefs of the fame fimple idea, in feveral fubjects, may be called *proportional* relations.

Another occafion of comparing things being taken from the circumftances of their origin, as father, fon, brother, &c. thefe may be called *natural* relations.

Sometimes the foundation of confidering things is fome act, by which any one comes by a moral right, power, or obligation, to do fomething: fuch are general, captain, burgher: thefe are *inftituted* and *voluntary* relations, and may be diftinguifhed from the natural, in that they are alterable and feparable from the perfons to whom they fometimes belonged, though neither of the fubftances fo related be deftroyed. But natural relations are not alterable, but are as lafting as their fubjects.

Another relation is the conformity or difagreement of men's voluntary actions to a rule, to which they are referred, and by which they are judged of: thefe may be called *moral* relations.

It is this conformity or difagreement of our actions to fome law (by which good or evil is drawn on us from the will and power of the law-maker, and is what we call *reward* or *punifhment*) that renders our actions morally good or evil.

Of thefe moral rules or laws there feem to be three forts, with their different enforcements. Firft, the divine law; fecondly, civil law; thirdly, the law of opinion or reputation. By their relation to the firft, our actions are either fins or duties; to the fecond, criminal or innocent; to the third, virtues or vices. Locke's Effay, vol. i. chap. 25, 26. 33.

Relation, in *Logic*, is an accident of fubftance, accounted one of the ten categories or predicaments.

Each fubftance admits of an infinity of relations. Thus the fame Peter confidered with regard to Henry, is in the relation of a mafter; with regard to John, in that of a tenant; with regard to Mary, in that of a hufband, &c. Again, with regard to one perfon, he is rich; with regard to another, poor; with regard to another, he is far, near, tall, fhort, a neighbour, ftranger, learned, unlearned, good, bad, equal, &c. It is difputed among the fchool philofophers, whether or no the relation be a thing formally and really diftinct from the foundation of the fubftance.

Relation, *Relatio*, in *Rhetoric*, is fometimes ufed to fignify the fame with *recrimination;* which fee.

Relation is alfo ufed, in the *School Theology*, to denote certain of the divine perfections, called *perfonal* ones; becaufe by thefe one Divine Perfon is referred to another, and diftinguifhed from it.

Hence the fchoolmen teach, that in God there is one nature, two proceffions, three perfons, and four relations.

Thefe relations are paternity, filiation, active fpiration, and paffive fpiration.

Relation, in *Geometry*, *Arithmetic*, &c. is the habitude, or refpect of two quantities to one another, with regard to their magnitude. This we more ufually called *ratio* or *reafon*. See Ratio.

The equality or famenefs of two fuch relations we call *proportion;* which fee.

Relation, in *Grammar*, is the correfpondence which words have to one another in *conftruction;* which fee. See alfo Regimen and Syntax.

Faulty and irregular relations are the things chiefly to be guarded againft in writing correctly; they make the fenfe obfcure, and frequently equivocal. Thus: the orator was attended to with a coldnefs, which was the more remarkable, as the audience were under fome emotion before he began. Here coldnefs being put indeterminately, the relative *which* can have no juft and regular relation to it.

Relation is alfo frequently ufed for analogy, or what feveral things have in common. See Analogy.

In painting, architecture, &c. a certain relation of the feveral parts and members of the building, or picture, conftitutes what we call *fymmetry;* which fee.

Relation, in *Law*, is where two things, as times, &c. are confidered as if they were one; the thing fubfequent being confidered as taking effect, by relation, at the time preceding.

As if A deliver a writing to B, to be delivered to C, as the deed of A; the writing fhall be deemed to be delivered to C, at the time when it was given to B, by relation.

When the execution of a thing is done, it hath relation to the thing executory, and makes all but one act to record, although performed at feveral times. (1 Rep. 199.) Judgment fhall have relation to the firft day of the term, as if given on that very day, unlefs there is a memorandum to the contrary; as where there is a continuance till another day in the fame term. (3 Salk. 212.) A verdict was given in a caufe for a plaintiff, and there was a motion in arreft of judgment within four days; the court took time to advife, and in four days afterwards the plaintiff died: it was adjudged, that the favour of the court fhall not prejudice the party, for the judgment ought to have been given after the firft four days; and though it is given after the death of the party, it fhall have relation to the time when it ought to have been given. (1 Leon. 187.) Rule was had for judgment, and two days after the plaintiff died; yet the judgment was entered, becaufe it fhall have relation to the day when the rule was given, which was when the plaintiff was alive. (Poph. 132.) Judgment againft an heir of the obligation of his anceftor fhall have relation to the time of the writ *firft* purchafed; and from that time it will

will avoid all alienation made by the heir. (Cro. Car. 102.) If one be bail for a defendant, and before judgment he leafes his lands; they fhall be liable to the bail, and judgment by relation.

By ftat. 29 Car. II. c. 3. § 16. writs of execution fhall bind the property of goods taken in execution, only from the time of their delivery to the officer. Sale of goods of a bankrupt, by commiffioners, fhall have relation to the firft act of bankruptcy; and be good, notwithftanding the bankrupt fells them afterwards. (Stat. Jac. I. c. 15.) If a man buys cattle in a market, which are ftolen, and felleth them out of the market, though the cattle are afterwards brought into the market, and the fecond bargain confirmed, and money paid, &c., this bargain will not be good; for it fhall have relation to the beginning, which was unlawful. (Dyer 99.) Fines, being but common affurances, fhall be guided by the indentures precedent; and the execution of them have relation to the original act. (Cro. Jac. 110.) Letters of adminiftration relate to the death of the inteftate, and not to the time when they were granted.

So bills in parliament to which the king affents on the laft day of parliament, fhall relate and be of force from the firft day thereof. Coke calls this *fictio juris*.

Relation, in *Mufic*. See Relatio.

RELATIVE Propositions, are fuch as include fome relation and comparifon.

Thus, where the treafure is, there will the heart be; As much as thou haft, fo much thou art worth, &c. are relative propofitions.

Relative *gravity*, *levity*, *motion*, *neceffity*, *place*, *fpace*, *time*, *velocity*. See the feveral fubftantives.

Relative *Terms*, in *Logic*, are words which imply a relation, or a thing confidered as compared to another.

Relative terms include a kind of oppofition between them; yet fo, as that the one cannot be without the other.

Such are *father* and *fon*, *hufband* and *wife*, *king* and *fubjects*, &c.

Relative, in *Grammar*, is a word or term, which in the conftruction anfwers to fome word foregoing, called the *antecedent*; which fee.

All relatives are faid to reciprocate, or mutually infer each other; and, therefore, they are often expreffed by the genitive cafe.

Relative *Pronoun*. See Pronoun.

RELATOR, in *Law*, a rehearfer, or teller, applied to an informer. See Information.

RELAXATION, in *Law*, is ufed for a *releafing*. See Release.

In this fenfe, we fay the relaxation of an attachment in the court of admiralty.

The tenor of indulgence is a relaxation, or a diminution, of the pains of purgatory.

Relaxation, in *Surgery*, is a preternatural extenfion, or ftraining of a nerve, tendon, mufcle, or the like; either through violence or weaknefs.

Hernias are defcents or relaxations of the inteftines, &c. From the fame caufe arife defcents or prolapfions of the anus, &c.

RELAY, a frefh equipage, horfe, &c. fent before, or appointed to be ready, for a traveller to change, to make the greater expedition; as in riding poft.

The term is borrowed from the French, *relais*, which fignifies the fame thing. In France, the general of the pofts entitles himfelf fuperintendant of the relays.

Relay *Horfes*, in the *Artillery*, are horfes that march with the artillery or baggage, and are ready to relieve others, or to affift in going up a hill, or through bad roads, &c.

Relays, in *Hunting*, are frefh fets of dogs, or horfes, or both, difpofed here and there for readinefs, in cafe the game come that way, to be caft off, or to mount the hunters in lieu of the former, which are fuppofed to want refpite.

Relay, in *Tapeftry*, is an opening left in a piece of tapeftry, where the colours or figures are to be changed; becaufe on thofe occafions, the workmen are changed; or elfe the places are left to be filled up, till the reft of the work is done. See Tapestry.

RELEASE, Relaxatio, in *Law*, denotes an inftrument, by which eftates, rights, titles, entries, actions, and other things, are fometimes extinguifhed and annulled, fometimes transferred, fometimes abridged, and even fometimes enlarged: and it is a fpecies of conveyance which prefuppofes fome other conveyance precedent, and ferves to enlarge, confirm, alter, reftrain, reftore, or transfer the intereft granted by fuch original conveyance.

A releafe is either in fact or in law. A releafe *in fact*, is that which the very words do exprefsly declare.

A releafe *in law*, is that which acquits by way of confequence, or intendment of law. A releafe is the giving or difcharging of a right of action, which a man hath claimed, or may claim, againft another, or that which is his: or it is the conveyance of a man's intereft or right which he hath to a thing, to another who hath poffeffion of it, or fome eftate in it. (4 New Abr.) According to Coke releafes are diftinguifhed into exprefs releafes in deed, and thofe arifing by operation of law; and are made of lands and tenements, goods and chattels; or of actions real, perfonal and mixed. (1 Inft. 264.) Releafes of land may enure, or take effect, either, 1. By way of *enlarging an eftate*, or *enlarger l'eftate:* as if there be tenant for life or years, remainder to another in fee, and he in remainder releafes all his right to the particular tenant and his heirs, this gives him the eftate in fee. (Litt. § 465.) But in this cafe the releffee muft be in poffeffion of fome eftate, for the releafe to work upon: for if there be a leffee for years, and, before he enters and is in poffeffion, the leffor releafes to him all his rights in the reverfion, fuch releafe is void for want of poffeffion in the releffee. (Litt. § 459.) But when it is faid, that a releafe, which enures by enlargement, cannot work without a poffeffion, it muft be underftood to mean, not that an actual eftate in poffeffion is neceffary, but that a "vefted intereft" fuffices for fuch a releafe to operate upon. By comparing this with the operation of a Lease *and Releafe* (which fee) it will be feen, that not only eftates in poffeffion, but eftates in remainder and reverfion, and all other incorporeal hereditaments, may be effectually granted and conveyed by leafe and releafe; but it is an inaccuracy to fay, that the releffees are, in thefe cafes, in actual poffeffion of the hereditaments: the right expreffion is, that they are actually vefted in him, by virtue of the leafe in poffeffion and the ftatute. 1 Inft. 270. (*a*) n. 3.

To make releafes operate by enlargement, it is generally neceffary, that the releffee, at the time the releafe is made, fhould be in actual poffeffion of, or have a vefted intereft in, the lands intended to be releafed; that there fhould be a privity between him and the releffor; and that the poffeffion of the releffee fhould be notorious.

2. By way of *paffing an eftate*, or *mitter l'eftate:* as when one or two co-parceners releafeth all her right to the other, this paffeth the fee-fimple of the whole. (1 Inft.

(1 Inft. 273.) And in both thefe cafes there muft be a privity of eftate between the releffor and the releffee; that is, one of their eftates muft be fo related to the other, as to make but one and the fame eftate in law. 3. By way of *paffing a right*, or *mitter le droit:* as if a man be diffeifed, and releafeth to his diffeifor all his right; hereby the diffeifor acquires a new right, which changes the quality of his eftates, and renders that lawful which before was tortious or wrongful. (Litt. §. 466.) 4. By way of *extinguifhment:* as if my tenant for life makes a leafe to A for life, remainder to B and his heirs, and I releafe to A; this extinguifhes my right to the reverfion, and fhall enure to the advantage of B's remainder as well as of A's particular eftate. (Litt. §. 470.) 5. By way of *entry and feoffment:* as if there be two joint diffeifors, and the diffeifee releafes to one of them, he fhall be fole feifed; and fhall keep out his former companion; which is the fame in effect as if the diffeifee had entered, and by that means put an end to the diffeifin, and afterwards had enfeoffed one of the diffeifors in fee. (1 Inft. 278.) And hereupon we may obferve, that when a man has in himfelf the poffeffion of lands, he muft at the common law convey the freehold by feoffment and livery; which makes a notoriety in the country: but if a man has only a right or a future intereft, he may convey that right or intereft by a mere releafe to him that is in poffeffion of the land: for the occupancy of the releffee is a matter of fufficient notoriety already. Blackft. Com. book ii. See LEASE *and Releafe*.

Littleton fays, that the proper words of a releafe are "remififfe, relaxaffe, and quietum clamaffe," which have all the fame fignification. Lord Coke adds, "renunciare, acquietare," and fays, that there are other words which will amount to a releafe; as, if the leffor grants to the leffee for life, that he fhall be difcharged of the rent; this is a good releafe. (Litt. § 445. 1 Inft. 264. Plowd. 140.) So a pardon, by act of parliament, of all debts and judgments, amounts to a releafe of the debt: the word pardon including a releafe. (1 Sid. 261.) An exprefs releafe muft regularly be in writing and by deed, according to the common rule, "eodem modo oritur, eodem modo diffolvitur," fo that a duty arifing by record muft be difcharged by matter of as high a nature: fo of a bond or other deed. (Co. Litt. 264. *b*. 1 Rol. Rep. 43. 2 Leon. 76. 213. 2 Rol. Abr. 408. 2 Sand. 49. Morr. 573. pl. 787.) But a promife by words may, before breach, be difcharged or releafed, by word of mouth only. (1 Sid. 177. 2 Sid. 78. Cro. Jac. 483. 620. See Cro. Car. 383. 1 Mod. 262. 2 Mod. 259. 1 Sid. 293.) A releafe of a right in chattels cannot be without deed. (1 Leon. 283.) A covenant perpetual, as that the covenantor will not fue beyond a certain limitation of time, is an abfolute releafe. But if the covenant be, that he will not fue *till* fuch a time, this does not amount to a releafe, nor is pleadable in bar as fuch, but the party hath remedy only on his covenant. If two are jointly and feverally bound in an obligation, and the obligee, by deed, covenants and agrees not to fue one of them; this is no releafe, and he may notwithftanding fue the other. (Cro. Car. 551. 2 Salk. 575.) But if two are jointly and feverally bound, a releafe to one difcharges the other. L. Raym. 420.

It feems agreed, that a will, though fealed and delivered, cannot amount to a releafe; and, therefore, where in debt on an obligation, by the reprefentative of a teftator, a defendant pleaded, that the teftator by his laft will in writing releafed to the defendant; this was adjudged ill, and that no advantage could be taken by plea. (1 Sid. 421.) But it hath been held in equity, that though a will cannot enure as a releafe, yet provided it were expreffed to be the intention of the teftator that the debt fhould be difcharged, the will would operate accordingly; and that, in fuch cafe, it would be plainly an abfolute difcharge of the debt, though the teftator had furvived the legatee. (1 P. Wms. 85. 2 Vern. 521.) If a debt is mentioned to be devifed to the debtor, without words of releafe, or difcharge of the debt, and the debtor die before the teftator, this will not operate as a releafe, but will be confidered as a lapfed legacy, and the debt will fubfift. (2 Vern. 522.) A debt is only a right to recover the amount of the debt by way of action; and as an executor cannot maintain an action againft himfelf, or againft a co-executor, the teftator, by appointing the debtor an executor of his will, difcharges the action, and confequently difcharges the debt. Still, however, when the creditor makes the debtor his executor, it is to be confidered merely as a fpecific bequeft or legacy, devifed to the debtor to pay the debt; and, therefore, like other legacies, it is not to be paid or retained till the debts are fatisfied; and if there be not affets for the payment of the debts, the executor is anfwerable for it to the creditors. In this cafe, it is the fame whether the executor accepts or refufes the executorfhip. On the other hand, if the debtor makes the creditor his executor, and the creditor accepts the executorfhip, if there be affets, he may retain his debt out of the affets againft the creditors in equal degree with himfelf; but if there be not affets, he may fue the heir, when the heir is bound. 1 Inft. 264. *b* in *n*. See EXECUTOR.

Littleton fays, that a releafe of all demands is the beft releafe to him, to whom it is made; and Coke fays, that the word "demand" is the largeft word in law, except "claim;" and that a releafe of all demands difcharges all forts of actions, rights, and titles, conditions before or after, breach, executions, appeals, rents of all kinds, covenants, annuities, contracts, recognizances, ftatutes, commons, &c. (Litt. § 508. Co. Litt. 291.) A releafe of all actions difcharges a bond to pay money on a future day. But a releafe of actions does not difcharge a rent before the day of payment. (Co. Litt. 292.) By a releafe of all manner of actions, all actions, as well criminal as real, perfonal and mixed, are releafed. Co. Litt. 287. See Jacob's Law Dict. by Tomlins.

RELEGATION, RELEGATIO, a kind of exile or banifhment, by which the obnoxious perfon is commanded to retire to a certain place prefcribed, and to continue there till he be recalled.

Lord Coke calls relegation a banifhment for a time only; Courtin more adequately defines relegation a banifhment to a certain place for a certain term.

In Rome, relegation was a lefs fevere punifhment than deportation, in that the relegated perfon did not thereby lofe the rights of a Roman citizen, nor thofe of his family, as the authority of a father over his children, &c.

RELHANIA, in *Botany*, received that name from the pen of the late M. l'Heritier, in honour of the Rev. Richard Relhan, F.R.S. and A.L.S., author of the Flora Cantabrigienfis. — L'Herit. Sert. Angl. 22. Schreb. 563. Willd. Sp. Pl. v. 3. 2135. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 91. Thunb. Prodr. 145. Poiret in Lamarck Dict. v. 4. 93. (Eclopes; Gærtn. t. 169. Lamarck Illuftr. t. 689.)—Clafs and order, *Syngenefia Polygamia-fuperflua*. Nat. Ord. *Compofitæ difcoideæ*, Linn. *Corymbiferæ*, Juff.

Gen. Ch. *Common calyx* oblong, imbricated, with oblong chaffy fcales. *Cor.* compound, radiated; united florets in the difk numerous, tubular, funnel-fhaped, fivecleft; female ones in the radius ligulate, ovate-oblong. *Stam.*,

Stam., in the perfect florets, filaments five, very fhort; anthers combined into a tube. *Pift.* in the perfect florets, germen oblong; ftyle fimple; ftigmas two, reflexed: in the female ones, germen oblong, rather incurved; ftyle fimple; ftigmas two, recurved. *Peric.* none, except the permanent unchanged calyx. *Seeds*, to all the florets alike, folitary, angular, with a membranous, many-cleft, fhort crown. *Recept.* chaffy.

Eff. Ch. Receptacle chaffy. Seed-crown membranous, fhort, cylindrical. Calyx imbricated, chaffy. Florets of the radius numerous.

M. l'Heritier diftinguifhes this genus from *Athanafia* by the prefence of a radius; from *Ofmites* by the florets of that radius producing perfect feeds; and from *Leyfera* by the want of a feathery feed-down. Gærtner remarks that his *Eclopes*, adopted from fir Joseph Banks's and Dr. Solander's papers, is nothing more than an *Athanafia*, furnifhed with a radius. A due attention to the fyngenefious clafs foon teaches us to miftruft this character, which is unftable, even in feveral fpecies of that clafs; witnefs the genera *Coreopfis* and *Bidens*. Still lefs is the fertility or barrennefs of the radiant florets capable of diftinguifhing natural genera, though Linnæus has, unadvifedly, founded a diftinction of orders, in the clafs in queftion, upon thofe differences. We cannot but affent, therefore, to the opinion of Poiret, that the genus of *Relhania* is not naturally diftinct from the Linnæan *Ofmites*, at leaft, which laft name being already eftablifhed, ought to have been retained. However ftriking the radiating, chaffy, fhining inner fcales of the calyx may be in a few fpecies of *Ofmites*; approaches towards that character are found in the *Relhaniæ*, as *genifti-folia*, and ftill more in *paleacea*. We are far from intending to do away the claims of our friend, Mr. Relhan, to botanical commemoration, even were that honour beftowed in general far lefs indifcriminately than it is. For the prefent, the *Relhania* of L'Heritier is received; and if that be at any time abolifhed, there ought to be one eftablifhed on more folid principles.

Willdenow has nineteen fpecies of this fuppofed genus; all natives of the Cape of Good Hope, moftly of a fhrubby bufhy habit, green-houfe plants in England, where only one of them indeed appears to be cultivated. Their flowers are moftly corymbofe, fmall, of a dull yellow, not remarkable for beauty. We felect a few examples.

R. *fquarrofa*. Hook-leaved Relhania. Willd. n. 1. Ait. n. 1. (Athanafia fquarrofa; Linn. Sp. Pl. 1180. Amœn. Acad. v. 6. 98. Santolina fquarrofa; Linn. Am. Acad. v. 4. 329.)—Leaves elliptical, pointed; recurved at the point.—Sent to Kew by Mr. Maffon, in 1794. It flowers in the green-houfe in May and June. The whole *fhrub* is fmooth, much branched. *Leaves* numerous, fomewhat imbricated, about a quarter of an inch long, elliptical, obfcurely fingle-ribbed beneath, entire, acute; ftrongly recurved, fmooth, finely dotted on both fides. *Flowers* folitary, on flender axillary ftalks, thrice the length of the leaves. *Calyx* about half an inch long, very fmooth, rather fhining. This fhould feem a different plant from *R. fquarrofa* of Thunberg, who defines his "with terminal umbels," and has thus led Willdenow, contrary to the defcription of Linnæus, to refer the fpecies in queftion to the firft fection of the genus, "*with aggregate flowers.*" It appears, by fpecimens in the Linnæan herbarium, that the *flowers* are fometimes fo crowded about the ends of the branches, as to affume a corymbofe appearance, though each ftalk is really axillary. Such a fpecimen probably was defcribed by Thunberg.

R. *geniftifolia*. Broom-leaved Relhania. Willd. n. 2. (Athanafia geniftifolia; Linn. Syft. Nat. ed. 12. v. 2. 540. Mant. 464.)—Leaves obovato-lanceolate, pointed, fingle-ribbed beneath, entire, fmooth, fomewhat imbricated. Flowers terminal, umbellate.—A bufhy *fhrub*, very much branched. *Leaves* a quarter of an inch, or hardly fo much, in length, numerous, crowded, dotted, entire, fmooth; the lower ones obovate, and fmalleft; the upper more lanceolate and elongated; all bluntifh, with a minute, often hooked, point, and fingle-ribbed at the back only. *Flowers* fmaller than the preceding, from five to eight together, in little terminal umbels. *Calyx* fhining.

R. *vifcofa*. Glutinous Relhania. L'Herit. Sert. 23. Willd. n. 5. (Eclopes vifcida; Gærtn. v. 2. 440. t. 169.)—Leaves linear-lanceolate, pointed, vifcid, obfcurely fingle-ribbed beneath, rather flefhy; the upper ones fomewhat crenate.—The *flowers* are much like the laft-mentioned; but the *leaves* are twice as large, more elongated in fhape, more flightly ribbed, the edges of the upper ones rough or crenate, and all of them extremely glutinous. When bruifed, the dried *leaves* are found to retain a powerful aromatic fcent, approaching to that of orange-peel.

R. *pedunculata*. Long-ftalked Dwarf Relhania. L'Herit. Sert. Angl. 23. Willd. n. 7. (R. pumila; Thunb. Prodr. 146. Athanafia pumila; Linn. Suppl. 362. Zoegea capenfis; ibid. 382.)—Leaves linear, villous, and glandular. Stem diffufe. Flower-ftalks axillary, much longer than the leaves.—A fmall herbaceous annual fpecies, whofe *root* is furnifhed with numerous capillary fibres. *Stem* a fpan high, branched from the bafe, round, purplifh, fpreading; glandular and flightly cottony in the upper part, as well as the *leaves*; which are about an inch long, very narrow, fomewhat triangular. *Flowers* fmall, yellow, on long, ftoutifh, downy, axillary ftalks, about the fummits of the branches. This occurs twice in the *Supplementum*, having, in one inftance, been defcribed by Linnæus himfelf, from a wild fpecimen, and in the other, adopted by his fon, unfeen, from Thunberg's communications.

R. *paleacea*. Chaffy-flowered Relhania. L'Herit. Sert. Angl. 24. Willd. n. 11. Thunb. Prodr. 146. (Leyfera paleacea; Linn. Syft. Veg. ed. 13. 641. L. ericoides; Berg. Cap. 294. Eclopes; Lamarck f. 2? Afterophorus fruticofus luteus, foliis rorifmarini crebris, ovariis hirfutis; Vaill. Act. German edition, 585.)—Leaves linear, triangular, channelled, hoary; recurved at the point. Flowers terminal, folitary, feffile. Calyx turbinate.—Communicated by Van Royen to Linnæus, and by Sherard, as it appears, to Vaillant. The *ftem* is fhrubby, a fpan high, branched. *Leaves* numerous, about an inch long, narrow, clothed, as well as the young *branches*, with fine hoary down. *Calyx* ovate, fmooth, a quarter of an inch in diameter; its inner fcales much elongated, lanceolate, acute, and membranous, refembling the fcales of the *receptacle*, which ftand prominent and erect, above the florets of the difk. This plant has fo much of the external afpect of *Leyfera gnaphalodes*, that we can hardly wonder at Linnæus, for having referred it, by the habit alone, to the fame genus. Upon a careful examination, however, the characters, and even the appearance, of the parts of fructification, are abundantly different in the two plants.

Moft of the other fpecies of *Relhania*, in Willdenow, are adopted from the fhort fpecific definitions of Thunberg and L'Heritier; nor have we been able to determine them all with certainty. It is remarkable that no figure of any has appeared, except in Gærtner and Lamarck, nor is the latter very happy or difcriminative, in what he has exhibited of this genus, called by him, after Gærtner, *Eclopes*.

RELICS, Reliquiæ, in the *Romifh Church*, certain remains of the body or clothes of fome faint or martyr, devoutly preferved in honour to his memory, carried at proceffions, kiffed, revered, &c.

The abufes of that church in point of relics have been very flagrant. F. Mabillon, a Benedictine, complains of the great number of fufpected relics expofed on altars: he owns, that were there to be a ftrict inquifition into the relics, vaft numbers of fpurious ones would be found offered every where to the piety and devotion of the faithful; and adds, that bones are frequently confecrated, fo far from belonging to faints, that, in all probability, they do not belong to Chriftians.

The catacombs are an inexhauftible fund of relics; yet it is ftill difputed who were the perfons interred in them.

In the eleventh century, a method was introduced of trying fuppofed relics by fire. Thofe which did not confume in the fire were reputed genuine; the reft not.

It is an ancient cuftom, which ftill obtains, to preferve the relics in the altars on which mafs is celebrated. To this purpofe, a fquare hole is made in the middle of the altar, big enough to receive the hand; and in that is the relic depofited, being firft wrapped in red filk, and inclofed in a leaden box.

The Romanifts allege a confiderable degree of antiquity in behalf of their relics. The Manichees, it feems, out of hatred to the flefh, which they held an evil principle, are recorded as refufing to honour the relics of faints; which is efteemed a kind of proof, that the Catholics did it in the firft ages.

Indeed, folly and fuperftition blended themfelves with religion at too early a period. Even the touching of linen cloths on relics, from an opinion of fome extraordinary virtue derived from them, appears to be as ancient as the firft ages; there being a hole made in the coffins of the forty martyrs at Conftantinople, exprefsly for this purpofe.

This practice of honouring the relics of faints, on which the church of Rome, in fucceeding ages, founded her fuperftitious and lucrative ufe of them, as objects of devotion, as a kind of charms or amulets, and as inftruments of pretended miracles, feems to have originated in a very ancient cuftom, that prevailed among Chriftians, of affembling at the cœmeteries or burying-places of the martyrs, for the purpofe of commemorating them, and of performing divine worfhip. When the profeffion of Chriftianity obtained the protection of the civil government, under Conftantine the Great, ftately churches were erected over their fepulchres, and their names and memories were treated with every poffible token of affection and refpect. (See Saints.) In procefs of time, this reverence of the martyrs exceeded all reafonable bounds; and thofe prayers and religious fervices were thought to have a peculiar fanctity and virtue, which were performed over their tombs. Hence probably proceeded the practice, already mentioned, which obtained in the fourth century, of depofiting relics of the faints and martyrs under the altars in all their churches. This practice, however, was then thought of fuch importance, that St. Ambrofe would not confecrate a church, becaufe it had no relics; and the council of Conftantinople in Trullo ordained, that thofe altars fhould be demolifhed, under which there were found no relics. The rage of procuring relics for this and other purpofes of a fimilar nature became fo exceffive, that, in 386, the emperor Theodofius the Great was obliged to pafs a law, forbidding the people to dig up the bodies of the martyrs, and to traffick in their relics.

Such was the commencement of that refpect for facred relics, which, in after ages, was perverted into a formal worfhip of them, and became the occafion of innumerable proceffions, pilgrimages, and miracles, from which the church of Rome hath derived incredible advantage. Towards the clofe of the ninth century, it was not enough to reverence departed faints, and to confide in their interceffions and fuccours: it was not enough to clothe them with an imaginary power of healing difeafes, working miracles, and delivering from all forts of calamities and dangers; their bones, their clothes, the apparel and furniture they had poffeffed during their lives, the very ground which they had touched, or in which their putrified carcafes were laid, were treated with a ftupid veneration, and fuppofed to retain the marvellous virtue of healing all diforders both of body and mind, and of defending fuch as poffeffed them againft all the affaults and devices of Satan. The confequence of this wretched notion was, that every one was eager to provide himfelf with thefe falutary remedies; for which purpofe, great numbers undertook fatiguing and perilous voyages, and fubjected themfelves to all forts of hardfhips; while others made ufe of this delufion, to accumulate their riches, and to impofe upon the miferable multitude by the moft impious and fhocking inventions. As the demand for relics was prodigious and univerfal, the clergy employed all their dexterity to fatisfy thefe demands, and were far from being nice in the methods they ufed for that end. The bodies of the faints were fought by fafting and prayer, inftituted by the prieft, in order to obtain a divine anfwer and an infallible direction; and this pretended direction never failed to accomplifh their defires: the holy carcafe was always found, and that always in confequence, as they impioufly gave out, of the fuggeftion and infpiration of God himfelf. Each difcovery of this kind was attended with exceffive demonftrations of joy, and animated the zeal of thefe devout feekers to enrich the church ftill more and more with this new kind of treafure. Many travelled with this view into the Eaftern provinces, and frequented the places which Chrift and his difciples had honoured with their prefence, that, with the bones and other facred remains of the firft heralds of the gofpel, they might comfort dejected minds, calm trembling confciences, fave finking ftates, and defend their inhabitants from all forts of calamities. Nor did thefe pious travellers return home empty; the craft, dexterity, and knavery of the Greeks found a rich prey in the ftupid credulity of the Latin relic-hunters, and made a profitable commerce of this new devotion. The latter paid confiderable fums for legs and arms, fkulls and jaw-bones, (feveral of which were Pagan, and fome not human,) and other things that were fuppofed to have belonged to the primitive worthies of the Chriftian church: and thus the Latin churches came to the poffeffion of thofe celebrated relics of St. Mark, St James, St. Bartholomew, Cyprian, Pantaleon, and others, which they fhew at this day with fo much oftentation. But there were many, who, unable to procure for themfelves thefe fpiritual treafures by voyages and prayers, had recourfe to violence and theft: for all forts of means, and all forts of attempts, in a caufe of this nature were confidered, when fuccefsful, as pious and acceptable to the Supreme Being.

Befides the arguments from antiquity to which the Papifts refer, in vindication of their worfhip of relics, of which the reader may form fome judgment from this article, Bellarmine appeals to fcripture in fupport of it, and cites the following paffages, *viz.* Exod. xiii. 19. Deut. xxxiv. 6. 2 Kings, xiii. 21. 2 Kings, xxiii. 16, 17, 18. Ifaiah, xi. 10. Matth. xi. 20, 21, 22. Acts, v. 12—15. Acts, xix. 11, 12. See Popery.

Relics are forbidden to be ufed or brought into England by feveral ftatutes; and juftices of peace are empowered to fearch houfes for Popifh books and relics, which, when found, are to be defaced and burnt, &c. 3 Jac. I. cap. 26.

RELICT, Relicta, in *Law*. See Widow.

RELICTA Verificatione, is when a defendant relinquifhes his proof or plea, and thereupon judgment is entered for the plaintiff.

RELIEF, Relevium, *Levamen*, a fine paid the chief lord, by a perfon at his coming to the inheritance of land held by military fervice.

This was faid *relevare hereditatem caducam;* and the money thus paid was called *relevamen*, *relevium*, or *relief*. Relief is ufually to the value of a year's rent or revenue.

The origin of the cuftom is thus: a feudatory or beneficiary eftate in lands being at firft only granted for life, after the death of the vaffal, it returned to the chief lord; and was hence called *feudum caducum*, *q. d.* fallen to the lord by the death of the tenant.

In courfe of time, thefe feudatory eftates being converted into inheritances by the connivance and confent of the lord; when the poffeffor of fuch eftate died, it was called *hæreditas caduca*, *q. d.* an inheritance fallen to the lord, from whom it was to be recovered, by the heir's paying a certain fum of money. But this fum was arbitrary, and at the will of the lord; fo that, if he pleafed to demand an exorbitant relief, it was in effect to difinherit the heir. The Englifh ill brooked this confequence of their new-adopted policy; and, therefore, William the Conqueror by his laws (cap. 22, 23, 24.) afcertained the relief, by directing (in imitation of the Danifh heriots), that a certain quantity of arms and habiliments of war fhould be paid by the earls, barons, and vavafours refpectively; and if the latter had no arms, they fhould pay 100*s*. William Rufus broke through this compofition, and again demanded arbitrary uncertain reliefs, as due by the feodal laws; thereby in effect obliging every heir to new-purchafe or redeem his land: but his brother Henry I. by his charter, reftored his father's law; and ordained that the relief to be paid fhould be according to the law fo eftablifhed, and not an arbitrary redemption. But afterwards, when, by an ordinance in 27 Hen. III. called the Affife of Arms, it was provided that every man's armour fhould defcend to his heir, for defence of the realm, and it thereby became impracticable to pay thefe acknowledgments in arms, according to the laws of the Conqueror, the compofition was univerfally accepted of 100*s*. for every knight's fee; as we find it ever after eftablifhed. (Glanv. l. ix. c. 4. Litt. § 112.) But it muft be remembered, that this relief was only then payable, if the heir at the death of his anceftor had attained his full age of twenty-one years.

Relief, *Reafonable*, called alfo *lawful* and *ancient* relief, is that enjoined by fome law, or fixed by ancient cuftom; and which does not depend on the will of the lord.

Thus in a charter of king John, mentioned by Matthew Paris:—"Si quis comitum vel baronum noftrorum, five aliorum tenentium de nobis in capite per fervitium militare, mortuus fuerit, & cum deceflerit, hæres fuus plenæ ætatis fuerit, & relevium debet, habeat hæreditatem fuam per antiquum relevium."

What this was, may be feen in the laws of William the Conqueror, &c. Bracton fays this fine was called a relief, "quia hæreditas, quæ jacens fuit per anteceffloris deceffum, relevatur in manus hæredum, &c."

A relief is alfo paid in focage-tenure, or petit ferjeanty; where a rent, or other thing, is paid by rendering as much as the rent or payment referved. But the manner of taking relief upon focage-tenure is very different from that upon tenure in chivalry. The relief on a knight's fee was 5*l*., or one-quarter of the fuppofed value of the land; but a focage-relief is one year's rent or render, payable by the tenant to the lord, be the fame either great or fmall (Litt. § 126.); and, therefore, Bracton (l. 2. c. 37. § 8.) will not allow this to be fo properly a relief, but "quædam præftatio loco relevii in recognitionem domini." So, too, the ftatute 28 Edw. I. c. 1. declares, that a free fokeman fhall give no relief, but fhall double his rent after the death of his anceftor, according to that which he hath ufed to pay his lord, and fhall not be grieved above meafure. Reliefs in knight-fervice were only payable, if the heir at the death of his anceftor was of full age; but in focage they were due even though the heir was under age, becaufe the lord has no wardfhip over him. (Litt. § 127.) The ftatute 12 Car. II. referves the reliefs incident to focage-tenures; and, therefore, whenever lands in fee-fimple are holden by a rent, relief is ftill due of common right upon the death of a tenant. 3 Lev. 145.

By the cuftom of Normandy, relief is due for lands held in villainage as well as in fee. By the cuftom of Paris, relief is not due upon inheritances in the direct line.

The quantity of the relief is very different; there are *fingle* reliefs, *double* reliefs, &c. The quality, too, is diverfe: there are *reliefs of property*, paid by the heir; *reliefs of bail*, or *tutorage*, paid by the guardian for his minor, or by the hufband for the fiefs of his wife, &c.; *relief of horfe and arms*, &c.

By the laws of king Canutus, the relief of an earl, paid to the king, was eight war horfes with their bridles and faddles, four cuiraffes, four helmets, four fwords, four hunting-horfes, and a palfrey. The relief of a baron or thane was four horfes, &c.

Relief, in *Chancery*, denotes an order fued out for the diffolving of contracts, and other acts, on account of their being unreafonable, prejudicial, grievous, or from fome other nullity, either *de jure*, or *de facto*.

Minors obtain relief againft acts paffed in their minority. Majors have relief in cafes of enormous damage, deceit, violence, over-reaching, extravagant bargains, &c.

Among the Romanifts it is a rule, that the church obtains relief any time, and againft all acts paffed in its prejudice; no prefcription prevailing againft it.

Relief, *Aid de*. See Aid.

Relief *of a Hare*, among *Hunters*, is the place where fhe goes to feed in the evening.

Relief, in *Sculpture*. See Relievo.

RELIEVE, in the *Military Senfe*. To relieve, is to take the poft of another body. Hence, to relieve the guard, to relieve the trenches, &c. is to bring frefh men upon the guard, or to the trenches, and to fend thofe to reft who have been upon duty before. They alfo fay, relieve a fentinel, which is generally done every two hours, by a corporal who attends the relief; relieve the fteerfman, &c.

To relieve a place that is befieged, is to furnifh it with a fupply of men, provifions, ammunition, &c.

RELIEVER, in *Artillery*, is an iron ring fixed to a handle by means of a focket, fo as to be at right angles to it. It ferves to difengage the firft fearcher of a gun, when any of its points are retained in a hole, and cannot be got out otherwife.

RELIEVING Tackles, in a *Ship*, are two ftrong tackles, ufed to prevent a fhip from overturning on the careen, and to affift in bringing her upright after that operation is completed. The relieving tackles are furnifhed with

with two ſtrong *guys*, or pendants, by which their efforts are communicated, under the ſhip's bottom, to the oppoſite ſide, where the ends of the guys are attached to the lower gun-ports. The other ends of the tackles are hooked to the wharf or pontoon, by which the veſſel is careened. Thus, if a ſhip is firſt to be laid down on the larboard ſide, which is neareſt the wharf, the relieving tackles are paſſed under her bottom from the ſaid wharf, and attached to the ſtarboard ſide, by which they will reſtrain her from falling lower than is neceſſary. Falconer.

Relieving *Tackle*, is alſo a name given to the train tackles of a gun-carriage.

RELIEVO, or Relief, *Imboſſment*, is applied to a figure which projects, or ſtands out prominent, from the ground or plane on which it is formed, whether that figure be cut with the chiſſel, moulded, or caſt. There are three kinds of relievo; *viz. alto, baſſo,* and *demi-relievo.*

Relievo, *Alto, haut relief,* or *high relievo,* is when the figure is formed after nature, and projects as much as the life.

Relievo, *Baſſo, bas relief,* or *low relievo,* is when the work is but raiſed a little from its ground, as we ſee in medals, and in the frontiſpieces or buildings, particularly the hiſtories, feſtoons, foliages, and other ornaments in friezes. See Basso *Relievo.*

Relievo, *Demi,* is when one-half of the figure riſes from the plane, *i. e.* when the body of a figure ſeems cut in two, and one-half is clapped on a ground. When in a baſſo relievo there are ſome parts that ſtand clear out, detached from the reſt, the work is called a *demi-boſſe.*

Relievo, in *Architecture,* denotes the ſally or projecture of any ornament.

This, Daviler obſerves, is always to be proportioned to the magnitude of the building it adorns, and the diſtance at which it is to be viewed.

If the work be inſulate, and terminated on all ſides, it is called a *figure in relievo,* or a *round emboſſment.* Such are ſtatues, acroters, &c.

Relievo, in *Painting,* denotes the degree of force or boldneſs by which a figure ſeems, at a due diſtance, to ſtand out from the ground of the painting, as if really imboſſed.

The relievo depends much on the depth of the ſhadow, and the ſtrength of the light; or on the light of the different colours bordering on one another; and particularly on the difference of the colour of the figure from that of the ground.

When the light is well choſen, to make the neareſt parts of figures advance; and well diffuſed on the maſſes, ſtill diminiſhing inſenſibly, and terminating in a large ſpecious ſhadow, brought off inſenſibly; the relievo is ſaid to be *bold,* and the claire obſcure, *well underſtood.*

RELIGION, Religio, that worſhip or homage that is due to God, conſidered as Creator, Preſerver, and, with Chriſtians, as Redeemer of the world.

The foundation of all religion is, that there is a God; and that he requires ſome acknowledgment and ſervice from his creatures.

Accordingly, religion, in the true meaning of the term, neceſſarily ſuppoſes and includes an intercourſe between God and man; *i. e.* on the part of God diſcoveries and manifeſtations of himſelf and his perfections, and of his will with regard to the duties which he requires; and on the part of man, a capacity and readineſs to receive and improve thoſe diſcoveries, and to conform to all the ſignifications of the divine will. For it is an undeniable principle, that whatſoever plainly appeareth to be the mind and will of God, whatever be the way in which we obtain the knowledge of it, we are indiſpenſibly obliged to obſerve. And as there are two ways by which God may be ſuppoſed to manifeſt himſelf and his will to mankind, *viz.* by his works and by his word, religion has been uſually diſtributed into *natural* and *revealed.* Theſe are not two kinds of religion, eſſentially different, much leſs contrary or contradictory to each other, becauſe they both have God for their object, and proceed from him; nor are they altogether the ſame, and differing merely in the mode of their communication. Although all true revealed religion muſt be conſiſtent with, and in no reſpect contrary to, the clear light of nature and reaſon, yet it may diſcover and reveal ſeveral things pertaining to truth and duty, which that light, if left to itſelf, could not have diſcovered at all, or not with ſufficient clearneſs and certainty. Theſe ſhould not be oppoſed to one another; nor is the one of them deſigned to exclude the other.

Religion, *Natural,* has been taken in different acceptations. Some underſtand by it every thing in religion, with regard to truth and duty, which, when once diſcovered, may be clearly ſhewn to have a real foundation in the nature and relations of things, and which unprejudiced reaſon will approve, when fairly propoſed, and ſet in a proper light. Accordingly ſome Chriſtian philoſophers and divines have comprehended under their ſcheme or ſyſtem of natural religion, a conſiderable part of what is contained in the ſcripture revelation, *e. gr.* the important truths and principles relating to the exiſtence, the unity, and attributes of God, his governing providence and moral adminiſtration, the worſhip that is due to him, the law that is given to mankind; or the whole of moral duty in its juſt extent, as relating to God, our neighbours, and ourſelves, the rewards and puniſhments of another ſtate, and other articles nearly connected with theſe, and dependent upon them. Having taken great pains to ſhew, that all this is perfectly agreeable to ſound reaſon, and founded in the nature of things, they have honoured the whole with the name of *natural religion.* None can heſitate to allow, that it is a real and great ſervice to religion to ſhew, that the main principles and duties of it are what reaſon muſt approve; and thoſe are unqueſtionably entitled to praiſe, who have undertaken to demonſtrate this with great clearneſs and force of argument. But it does not follow that, becauſe theſe things, when once clearly diſcovered, may be proved agreeable to reaſon, and to have a real foundation in the nature of things, reaſon alone, in the preſent ſtate of mankind, if left to itſelf, without higher aſſiſtance, would merely, by its own force, have diſcovered all of them, with their genuine conſequences, and have applied them to their proper uſes, for directing men in the true knowledge and practice of religion. Many things, ſays Mr. Locke, in his "Reaſonableneſs of Chriſtianity," are taken for unqueſtionable truths, and eaſily demonſtrable, without conſidering how long we might have been in doubt or ignorance reſpecting them, if revelation had been ſilent. Native and original truth is not ſo eaſily wrought out of the mine, as we who have it ready dug and faſhioned to our hands, are apt to imagine To the ſame purpoſe Dr. Clarke obſerves, (Diſc. on Nat. and Rev. Religion,) that it is one thing to ſee, that theſe rules of life, which are before-hand plainly and particularly laid before us, are perfectly agreeable to reaſon, and another thing to find out theſe rules merely by the light of reaſon, without their having been firſt otherwiſe made known. Accordingly ſome able and ſtrenuous aſſertors of natural religion, or the law of nature, though they contend that it is founded in the nature of things,

things, and agreeable to right reafon, derive the promulgation of it from divine revelation. Hence it may be concluded, that natural religion, or the Law *of Nature* (which fee), is not fo called, becaufe it was originally difcovered by natural reafon, but becaufe, when once made known, it is what the reafon of mankind, duly exercifed, approves, as founded in truth and nature.

Natural religion, in the fenfe now explained, is very confiftent with the fuppofition of an extraordinary divine revelation, for the purpofe of difcovering and promulgating it at firft, and alfo of re-eftablifhing and confirming it, when, through the corruption of mankind, the important principles and duties of it were funk into fuch darknefs, and fo confounded with pernicious errors, that an extraordinary affiftance was neceffary to recover men to the right knowledge and practice of it.

Natural religion is underftood by others in a fenfe which is abfolutely exclufive of all extraordinary revelation, and in direct oppofition to it. By natural religion, they mean that religion which men difcover by the fole exercife of their natural faculties and powers, without any other or higher affiftance. Thefe perfons difcard all pretences to extraordinary revelation, as the effects of enthufiafm or impofture. It is in this fenfe, that thofe who call themfelves Deists (fee that article) underftand natural religion, which they highly extol as the only true religion, the only difcovery of truth and duty upon which we may fafely depend; and which comprehends the whole of what is neceffary to be known and done, in order to our obtaining the favour of God, and attaining to true happinefs. But thofe who take natural religion in this fenfe entertain different opinions of the fubject, and exprefs their fentiments varioufly. The ableft advocates for natural religion, as oppofed to revelation, maintain, that it is clear and obvious to the whole human race, and that all men have a natural knowledge of it. They argue, that fince religion is equally the concern of all mankind, the wifdom and goodnefs of God require, that it fhould be actually known to all. To this purpofe is the reafoning of lord Herbert, who alleges, that God hath imprinted on the minds of all men innate ideas of the main principles of religion and morality. Tindal alfo, and the author of "Chriftianity as old as the Creation," argue in a fimilar manner: the former afferts, that this clear univerfal light that fhines into the minds of all men cannot be made clear to any man by an external extraordinary revelation: with the latter it is a kind of fundamental principle, that the law, or religion, of nature was a perfect fcheme of religion and morality, fairly drawn on the mind and heart of every man, in fuch a manner, that it is not poffible for any man to miftake it: and he even affirms, that the moft illiterate of the human race have naturally and neceffarily a clear and intimate perception of the whole of religion and of their duty. Hence it will be eafily owned, that there is no need of an extraordinary revelation to teach men what they all naturally and neceffarily know. This fcheme, however plaufible it may at firft appear, and though it feems to exhibit a beautiful reprefentation of the dignity of our fpecies, and of the univerfal goodnefs of God to the human race, appears to be altogether vifionary, when brought to the teft of fact and experience: whilft it fuppofes, that religion, in its true nature and juft extent, is naturally known to all men, fo that they cannot miftake it, it contradicts the teftimony of the authentic hiftory of mankind in all ages, which evinces that they have miftaken religion in its important principles and obligations.

Senfible of the inconveniences of this fcheme, others, by natural religion, underftand not merely that which is naturally and neceffarily known to all men, but that which reafon, duly exercifed and improved, is able, by its own natural force, to difcover, without the affiftance of any extraordinary revelation. In order to form a juft conception of this theory, we might inveftigate the extent of the powers and abilities of human reafon in judging concerning matters of religion, independently of all revelation: but without entering on a fpeculation of this kind, the difquifition of which would be more curious in the procefs than fatisfactory in the refult, we fhould recur to the fureft and plaineft mode of judging, which is the examination of the conclufions that may be deduced from fact and experience. Let us then inquire, what hath human reafon actually done in this way, by its own force, without any extraordinary affiftance? The fatisfactory anfwer to this inquiry cannot be obtained from any fyftems formed by perfons who have lived in ages and countries which have enjoyed the light of divine revelation; fince in this cafe it may reafonably be fuppofed, that they have borrowed light from revelation, though they are not willing to acknowledge it, or may not themfelves be fenfible of it. Syftems, therefore, that have been drawn up by our modern admirers of natural religion in Chriftian countries, cannot be alleged in proof of the force of unaffifted reafon in matters of religion; and the fame may be faid of thofe Pagan philofophers who have lived after Chriftianity had made fome progrefs in the world. Nor can we fairly infer the fufficiency of the light of natural reafon, without the aid of revelation, from the fyftems of the ancient philofophers, lawgivers, and moralifts, who lived before the Chriftian revelation was publifhed; unlefs it can be fhewn, that they themfelves derived the religious and moral principles which they taught, folely and entirely from the refearches and difquifitions of their own reafon, and difclaimed their having had any affiftance, with regard to thofe truths and principles, from tradition or divine inftruction. And it is no hard matter to fhew, by teftimonies from the moft celebrated ancients, that this was not the cafe, nor was it what they affumed to themfelves. It is well known, that the moft admired philofophers of Greece did not pretend to fet up merely on their own ftocks, but travelled into Egypt, and different parts of the Eaft, for the purpofe of improving their knowledge by converfation with the fages of thofe countries; who themfelves profeffed to have derived their knowledge, not merely from the difquifitions of their own reafon, but from a higher fource, from very ancient traditions, to which, for the moft part, they affigned a divine original. After all it muft be allowed, that the moft celebrated and fagacious of the ancient philofophers made pathetical complaints of human darknefs and ignorance, and of the great difficulties they experienced in fearching after truth. Many of them were fenfible of the great need there was of divine inftruction and affiftance, for enlightening and directing mankind in matters of religion and their duty: fo that no argument can be juftly drawn from the wife men and philofophers among the ancients, to fhew that the knowledge of what is ufually called natural religion, in its juft extent, is wholly and originally owing to the force of human reafon, exclufive of all divine revelation. And perhaps, fays the excellent writer whofe obfervations we are now citing, it would not be eafy to mention any nations, among whom any true knowledge of religion has been preferved, concerning which we can be affured, that they never had any benefit from the light of divine revelation; and that the principles of religious truth and duty, which were to be found among them, were originally the mere product of natural reafon, without any higher affiftance. Several things may be obferved among them, which feem to be the remains of an ancient univerfal tradition, or primeval religion, derived from the remoteft antiquity, and which, probably, had their original fource in divine revelaton, though in procefs of time it was greatly altered and corrupted. Leland's Advantage and Neceffity of the Chriftian Revelation, vol. i. § 1.

Religion, *Revealed*, is commonly underftood to be that knowledge of religion, which was originally communicated from God to men in a way of extraordinary revelation, for inftructing them in important religious truth, and directing and engaging them to the practice of their duty. In a general fenfe, all truth, and the manifeftation of it, may be faid to come from God, even that which we difcover in the ordinary ufe of thofe rational faculties which God hath given us. But revealed religion, as diftinguifhed from that which is ufually called natural, denotes that knowledge of religion which was originally communicated in an extraordinary and fupernatural way. Leland, ubi fupra. See Revelation.

The firft kind of religion, above-mentioned, or natural religion, flows immediately from the relation between the creature and the Creator; the latter, or revealed religion, does not follow from fuch a relation, but is fuperadded from the mere will and pleafure of the Creator.

The firft we ordinarily call morality, or ethics; becaufe immediately converfant about the manners and duties of men towards one another; and towards themfelves, confidered as creatures of that Being. See Ethics, Morality, and *Moral* Philosophy.

The latter we call, by way of eminence, religion, as being the rule of our duty immediately to God himfelf.

The firft fuppofes a God, a providence, and a future ftate, of rewards and punifhments; the latter likewife fuppofes an immediate miffion from God himfelf, attefted by miracles, &c. See Christian *Religion*.

Religion is more particularly ufed for that fpecial fyftem of faith and worfhip, which obtains in a particular age, fect, or country, &c.

In this fenfe we fay the Romifh religion, the Reformed religion, the religion of the Greeks, the Mahometan religion, the Jewifh religion, &c. See Judaism, Mahometanism, &c.

The Siamefe hold the diverfity of religions, *i. e.* the different manners of honouring God, to be pleafing to him; inafmuch as they have all the fame object, and all tend to the fame end, though by different means. Claude.

This fentiment of thefe idolaters is doubtlefs more juft than that of our zealots, who hold all but thofe of their own religion odious to God. The feveral fects in religion fee under their proper articles. See alfo Sect.

Of the religion of the ruling part of the world, you may find a lively defcription in a chorus in Seneca's Troas, at the end of the fecond act, beginning thus: "Verum eft, an timidos fabula decipit? umbras corporibus vivere conditis, &c." This, according to Patin, is the religion of princes, and great men, of magiftrates, monaftic fuperiors, and even fome phyficians and philofophers. M. Du Maine, head of the leaguers in France, ufed to fay, that princes have no religion till after they are turned of forty. "Cum numine nobis mors inftat, majore facit." Patin. Lett. Choif. 106.

Under this article we are naturally led to difcufs the fubject of national religion, in its connection with religious eftablifhments. It muft appear, on the flighteft reflection, that religion has a very confiderable influence, not only on the difpofition and character of individuals, but on the ftate of fociety in general. Accordingly legiflators and rulers have often found it one of the moft powerful inftruments of civil policy; and the hiftory of almoft every country affords numerous inftances of its being an excellent ally to the power of the civil magiftrate, or the moft dangerous rival. By religion we now mean that principle which influences men by the dread of evil or the hope of reward, from unknown and invifible caufes; whether the good or the evil be expected to take place in this world or in another; and in this general fenfe of the term, it comprehends enthufiafm, fuperftition, and every other fpecies of falfe religion as well as the true. It would lead us too far, if we attempted to trace the influence of this principle in the more barbarous or more civilized nations of antiquity. Enthufiafm and fuperftition have been more powerful and more efficacious on many occafions, which hiftory records, than political wifdom in the cabinet, or martial fkill and valour in the field. In fome cafes religion has concurred with the views of the civil magiftrate; and in others, it has counteracted them even in favour of the beft interefts of mankind. It is an obfervation of Mr. Hume's, that the precious fparks of liberty were kindled and preferved by the Puritans in England, and that it is to this fect, whofe principles appear fo frivolous, and whofe habits fo ridiculous, as he fomewhat invidioufly defcribes them, that the Englifh owe the whole freedom of their conftitution. The affertion, however, is too general. The capital advantage derived from Chriftianity in this weftern part of the world, is the total abolition of flavery, in confequence of its raifing men's ideas of the importance of the human fpecies. It is a memorable fact, that after the introduction of Chriftianity into the Roman empire, every law which was made relating to flaves was in their favour, till at laft all the fubjects of the empire were reckoned equally free. Although, in later times, flavery has been revived and continued, for commercial purpofes, in countries calling themfelves Chriftian, we truft that laudable efforts, originating in the liberal fentiments and affections which Chriftianity inculcates, will be crowned with fuccefs, and gradually annihilate this nefarious kind of traffick in every nation of the globe. Chriftianity, indeed, is almoft incompatible with abfolute defpotic power, both in fovereigns and private perfons. The corruptions of Chriftianity, exemplified in the exorbitant power of the pope, and the fuperftition of the Popifh worfhip, have been indirectly productive of confiderable benefit. The union of the weftern churches under one fupreme pontiff facilitated the intercourfe of nations in barbarous ages; and the pomp of the Popifh power contributed in no fmall degree towards preventing the fine arts from being totally loft in the barbarifm of Europe, and to their fubfequent revival, previoufly to that of literature and fcience in this weftern part of the world. Erroneous notions of religion, and the fuperftition blended with its purer principles, have been, however, the occafion of the moft lamentable evils in the government of ftates. Beccaria fays, in his "Effay on Crimes and Punifhments," that more than 100,000 witches have been condemned to die by Chriftian tribunals. Falfe principles of religion have encouraged men to commit the moft horrid crimes; and to inflict tortures both on themfelves and others, which cannot be thought of without horror. The hiftorical page of perfecution is ftained with blood. But it is our prefent defign to fketch out the benefits refulting from religion to civil fociety, rather than the evils which the perverfion of its principles and genuine fpirit have produced. It is natural to imagine, that the civil magiftrate would take religion under his protection with a view to thefe benefits; neverthelefs, it is much to be lamented that by erroneous notions of its nature and defign, and a mifapplication of its influence, it has been rendered the in-

ftrument

ftrument of tyranny and oppreffion. If magiftrates and rulers availed themfelves of the affiftance which religion affords for meliorating the character and condition of the members of the community over which they prefide; if they patronized and encouraged the principles and profeffion of it for the purpofe of reftraining the profligate and vicious, and of promoting a virtuous conduct with a view to the welfare and profperity of the ftate; and if they made ufe of the mighty powers with which religion furnifhes them merely for the purpofe of maintaining order and peace in the community to which they belong, and of fecuring and advancing its true interefts; there could be no reafon for alarm or complaint. Religion and civil government might unite their efforts for fuch laudable purpofes, and co-operate in promoting them, without any apprehenfion of danger; but lamentable experience has teftified that in too many inftances religion has been made fubfervient to ambition and worldly policy, infomuch that many perfons of juft reflection and comprehenfive views have dreaded the interference of civil governors in matters of religion. If, in fome cafes, they have done good, in others their interference has been pernicious, not only to religion, which has been thus corrupted and degraded, but to the civil community itfelf. Neverthelefs the opinion, that it is neceffary for the ftate to prefcribe the principles, and to regulate the modes of religion, has been almoft univerfally prevalent.

We are thus led briefly to difcufs the fubject of national eftablifhments of religion; and that we may do this without prejudice and partiality, we fhall ftate the arguments on both fides of the queftion, as much as poffible in the language of thofe who oppofe, and of thofe who defend them. Amongft thofe who have thought freely, and who have written as freely on this fubject, we find fome who contend againft eftablifhments in any degree whatever. They will not allow that religion fhould receive any fupport from the ftate, but infift that it ought to be left entirely to its own operation. There is naturally, they fay, no more connection between civil government and religion, than between the former and any thing elfe that depends upon opinion; lefs than the bufinefs of philofophy or religion. Becaufe thefe refpect the prefent life, with which civil governors have to do; whereas religion refpects the life to come, with which they have nothing to do. However, the conclufivenefs of this kind of reafoning feems to be materially affected by our preliminary remarks. Religion, it is faid, is a concern that lies out of the proper province of the civil magiftrate. Its object is invifible; its principles and affections, which are the fprings of moral and religious conduct, as well as its motives and fanctions, are not fubject to the direction and controul of fecular counfel and power; its feat is the underftanding and heart: nor is the external conduct, to which alone the cognizance of the civil magiftrate extends, of any importance in a moral view, independently of the internal principles in which it originates, and by which it is guided and governed. Befides, it has been urged that civil rulers have no right to prefcribe to the judgment in the province of religion, or to frame and enforce rules of moral conduct, for the obfervance or violation of which mankind are accountable only to God; nor are they competent or qualified for the exercife of fuch high powers. And if they cannot controul the faculties of the mind, their influence on the profeffion and practice, and that outward conformity to modes and rites of a religious nature which they may enforce, without the confent of the judgment and concurrence of the will, are calculated to do much greater harm than good; and to add to the number of hypocrites or martyrs. As the civil magiftrate cannot beftow the rewards, nor inflict the punifhments, that are appropriate to religion; and as he cannot eftimate the moral worth or demerit of his fubjects, he cannot, without culpable prefumption, affume, nor without intruding on the province of the fupreme and almighty God, exercife the authority of a fpiritual and final judge. Civil governors in general, fuch are their rank and ftation, the courfe of their education, and the habits of their lives, are lefs able than many others of lower condition, but of different views and connections, to decide concerning religious truth, or to determine who are qualified to advife and affift them. Moreover, it has been obferved, that neither magiftrates nor their ecclefiaftical advifers are warranted to eftablifh a ftandard either of religious faith or moral conduct, to which all the members of a community are required to conform, and from which they are not allowed to deviate without incurring fome lofs or damage. Such a ftandard, let it be ever fo liberally framed, or ever fo mildly enforced, is not likely to be fo comprehenfive, as to include all the teachers and all the profeffors of religion, who are entitled to the protection of the ftate in which their lot is caft. Befides, if fuch a ftandard of faith and practice could be devifed, thofe who object to religious eftablifhments on the ground now ftated, conceive, that their civil rulers have no right to eftablifh and impofe it; and thus to deprive perfons, who cannot approve it, of worldly honours and benefits, to which they have naturally an equal claim with others of their fellow-fubjects;—a claim, which they do not forfeit by the exercife of their own judgment in the province of religion. It has alfo been argued, that Chriftianity, fo far from countenancing, rather difcourages every kind of religious eftablifhment, that interferes with the right of private judgment. The language of the divine Author of our holy religion is, "Render to Cæfar the things that are Cæfar's, and to God the things that are God's;—Search the fcriptures;—Call no man mafter on earth;—My kingdom is not of this world." And that of his apoftles, "Let every man be fully perfuaded in his own mind;—Judge ye what I fay;" &c. &c. The adverfaries of eftablifhments allege, that a national church, conftituted by the civil magiftrate, and governed by laws enacted by his authority, and the Chriftian church, founded on the doctrine of Chrift and his apoftles, are effentially diftinct; and they fay, that fuch a church, *e. gr.* the church of England, lefs exceptionable than many others, which claims and exercifes, according to its 20th article, "power to decree rights and ceremonies, and authority in matters of faith," has, agreeably to the true nature and conftitution of the Chriftian church, no fuch power and authority; that it is inconfiftent with the allegiance which Chriftians, as the fubjects of Jefus Chrift, owe to him, the only lawgiver and king in the church; who, as they fay, hath exprefsly commanded that no power of this kind fhall ever be claimed, or ever be yielded by any of his followers. In the profecution of this mode of reafoning, they farther add, that if the church of England hath really this authority and right, the church of Rome had it before, and, as the elder and mother-church, ought to have been obeyed; and confequently the reformation, as it has been called, was a rebellion againft fuperiors, a difobedience to the authority vefted in the church, and ought, as fuch, to be renounced by returning to the church of Rome. They alfo argue, that this power to order the manner of God's worfhip, and to fettle articles of faith, is not at all lodged in the bifhops or clergy, who are the fpiritual paftors and guides in the eftablifhed church, but entirely in the king and parliament of thefe realms. So far were the bifhops and clergy from having any concern in the firft forming our prefent eftablifhed church,

or

or in ordering its rites and articles of faith, that it was done not only without, but in actual opposition to them. Hence they conclude, that the church of England is, in reality, a parliamentary church; that it is not, properly, an ally, as some have asserted, but a mere creature of the state. It depends entirely upon the acts and authority of parliament for its very essence and frame. The qualifications of its ministers, their power to officiate, the manner in which they are to administer the sacraments, are all limited and prescribed by authority of parliament; and this authority, which at first made, can alone alter and new-make it; can abolish, or add to its articles or rites, according to its pleasure, even though the whole body of bishops and clergy ever so much dislike or protest earnestly against it.

If it be asked, how came the civil magistrate to possess the authority which he exercises in the church of Christ? The objectors to establishments reply, that the subjection to higher powers, and obedience to magistrates, which the scriptures enjoin on Christians, relates only to civil, and not at all to religious matters, for this obvious reason, that the magistrate was at that time every where Pagan. They say, that Christianity is so far from enjoining, that it actually forbids, obedience to civil governors in things of a religious nature. It commands us "to call no man upon earth father or master" (Matt. xxiii. 8, 9.), *i. e.* to acknowledge no authority or jurisdiction of any in matters of religion, but to remember, that "one, one only is our master" and lawgiver, even Christ, and that all Christians are brethren: and that, though "the princes of the Gentiles exercise dominion over them, and they who are great exercise authority upon them, yet it shall not," says our Lord, "be so amongst you." (Matt. xx. 25.) Christ's kingdom is not of this world, and of course he is the sole lawgiver, judge, and sovereign in religious matters. (See Matt. xxiii. 8. xxviii. 18, 19. 1 Cor. viii. 6. Ephes. i. 22.) In the church of Christ, it is said, all authority and jurisdiction are vested originally in him, and flow from him, nor can any one lawfully exercise them without a commission from him; but in the church of England, the king, or queen, is "supreme head," possessing "all power to exercise all manner of ecclesiastical jurisdiction, and archbishops, bishops, archdeacons, and other ecclesiastical persons, have no manner of jurisdiction ecclesiastical, but by and under the king's majesty, who hath full power and authority to hear and determine all manner of causes ecclesiastical; and to reform and correct all vice, sin, errors, heresies, enormities, abuses whatsoever, which by any manner of spiritual authority or jurisdiction, ought, or may be lawfully reformed." (26 Hen. VIII. cap. 1. 37 Hen. VIII. cap. 17. 1 Eliz. cap. 1.) At the first establishment of this church under Henry VIII. and Edward VI. all the bishops took out commissions from the crown, for the exercising of their spiritual jurisdiction in these kingdoms, during the king's pleasure only; "and in their commissions acknowledge all sorts of jurisdiction, as well ecclesiastical as civil, to have flowed originally from the regal power, as from a supreme head, and a fountain and spring of all magistracy within his own kingdom." Burnet's Hist. Reform. part ii. Col. p. 92.

Yea, even the power of ordination itself, which is reckoned a peculiar of the episcopal office, the first reformers and founders of this church derived from the king, and exercised only as by authority from him, and during his pleasure. "Thus Cranmer, archbishop of Canterbury, Bonner, bishop of London, &c. took out commissions from the crown, importing, that because the vicegerent (Cromwell, a lay person) could not personally attend the charge in all parts of the kingdom, the king authorises the bishop, in his, (the king's or perhaps the vicegerent's) stead to ordain, within his diocese, such as he judged worthy of holy orders; to collate to benefices; to give institution; and to execute all other parts of the episcopal authority; and this during the king's pleasure only."

In consequence of this supremacy, the king or queen of this church hath power to excommunicate from, or to re-admit into it, independent of, yea, in direct opposition to, all its bishops and clergy. The king or queen revoke, if they please, any spiritual censures of the bishops or archbishops; yea, can suspend, deprive, or even excommunicate, themselves; or can, by their proclamation only, without the least confession, humiliation, or satisfaction for their offence, pardon and restore excommunicated persons, the vilest offenders, to the church's bosom again.

Yea, further, they have power to forbid all preaching for a time; as did king Henry VIII. king Edward VI. queen Mary, and queen Elizabeth; to limit, instruct, and prescribe to the clergy what they shall, and what they shall not preach; as did queen Elizabeth, king James I. king Charles I. king William, &c. Finally, to the king or queen only does it pertain to declare what is heresy, and authoritatively to pronounce what doctrines and tenets are, and what are not, to be censured as such: nor have all the bishops and clergy, assembled in convocation, the least authority to censure any tenet as heretical, if the prince on the throne refuse his consent.

Accordingly, the objectors to religious establishments allege, that in Christ's church, himself is the only sovereign and head; he only hath power to decree ceremonies and rites, to fix terms of communion and authority in points of faith: nor hath any earthly prince power to make laws in his kingdom, which shall bind the conscience of his subjects; or sovereignly to dictate to his servants and ministers what they shall believe, and what they shall preach. Yea, his subjects are expressly commanded and charged to receive nothing as doctrine or parts of religion, which are only commandments of men.

But in the church of England there is another sovereign, lawgiver, supreme head, besides Jesus Christ; an authority which commands things which Christ never commanded, which teaches doctrines he never taught, which enjoins terms of communion, and rites of religious worship, which Christ never enjoined. Hence they conclude, that these two churches are two distinct and quite different societies, framed after different models, consisting of different members, and governed by different officers, statutes, and laws. Whilst the objectors to established forms of worship esteem and reverence the great number of illustrious and excellent persons, both clergy and laity, of which the church of England can boast, they suggest, that the present established forms were drawn up when this kingdom just emerged out of Popish darkness; that in drawing them up special regard was had to the weakness of the people at that time, who could not be all at once entirely brought off from the old ceremonies and forms; and that there are several parts of our liturgy and ecclesiastical constitution, which even many of our bishops and clergy wish to see altered. Schemes have been proposed, and attempts have been made for omitting what is offensive, for correcting what is easily capable of amendment, and for accommodating the doctrine and forms of the established church, to the present advanced state of knowledge, and to the corresponding liberality of the modern professors of religion, both in and out of the church; but they have hitherto been unavailing: and it has been thought, that an exclusive establishment, appropriating to itself distinguished honours and benefits of a secular nature, and exposing those whom

whom it does not comprehend to privations, both of emolument and honour, has a tendency to difcourage every effort for improving its conftitution, and enlarging its boundaries. Some have alfo been of opinion that it reftrains freedom of inquiry, embarraffes integrity, and too much difpofes the uninftructed and uninformed to intolerance and perfecution. From whom, it has been faid, is a reform to be expected, but from thofe who have reafon for wifhing every thing to continue in ftatu quo? The dignitaries of the church, whofe emoluments induce them to reft fatisfied, and the ruling magiftrates of the ftate, who wifh things to remain quiet, and the great body of the laity, connected in one way or other with ecclefiaftical eftablifhments, cannot be fuppofed to be very anxious about a change in the conftitution of the church: nor will they be at a lofs for plaufible reafons for refifting any material alteration. The church and the ftate are fo incorporated, that nothing but a revolution, as it has been faid, in the latter, would caufe any very important amendment in the former. Neverthelefs, reformers have maintained, that if the liturgy, clergy, articles, canons, with all the ceremonies and rites of the eftablifhed church, were entirely vanifhed from the land; if its immenfe revenues were applied to eafe our heavy taxes, and for the payment of the public debts; and if preachers were paid only by voluntary contributions; the ftate would not fuftain fo effential a lofs and damage, that it could not thenceforward poffibly fubfift. Would, fay they, the Britifh monarchy be overthrown; our courts of judicature be fhut up; the courts of law be ftopped; parliaments no more meet; commerce and trade ftagnate, becaufe the national church was no more? On the contrary, however great the convulfion might be, the government, both civil and military, might remain the very fame. A timely reformation, however, would, as they imagine, prevent its total deftruction, and contribute to its permanence and profperity.

Some notice fhould here be taken of the learned Warburton's famous argument in favour of an eftablifhed church. The church, fays this prelate, has, by contract or alliance, refigned her fupremacy in matters ecclefiaftical, and her independency, to the ftate. In confequence of this, the ftate hath drawn up for her articles of faith, and forms of public worfhip, which it requires the church to fubfcribe and ufe. This alliance is a mere phantom, created by the warm imagination of the paradoxical bifhop, whofe ingenuity and learning have not been fufficient to render it popular, even among the moft zealous advocates of religious eftablifhments. Neither our hiftory nor our laws know any thing at all of it. The nature of our conftitution utterly difowns it; and avows the church to be not an ally, but a fubject to the ftate. An alliance fuppofes independency in the powers between which it fubfifts. But it is needlefs to enlarge on this topic.

Whilft it is allowed that religion has an influence on the conduct of men in this life, it is pleaded, on the other hand, that this beneficial influence of religion is promoted in all denominations of Chriftians, and as much in thofe which are reprobated by the ftate as in thofe which are encouraged by it. It has been alfo faid, that the fubject of religion is fo interefting to the generality of mankind, that if government did not interfere, the contention about it would be fo violent, that the public peace could not be preferved. To this argument in favour of eftablifhments, it has been replied, that thefe contentions are much increafed by the favour fhewn to one mode of religion, and the opprobrium which is confequently thrown on the reft; and that, where temporal intereft is not concerned, mere opinions will not occafion any differences at which government need to be alarmed. Chriftianity was introduced and eftablifhed, and fubfifted for about three hundred years, without any favour or protection from the governing powers; and the example of America, in fome provinces of which there is, ftrictly fpeaking, no eftablifhment of religion, and in which numerous forms of religion are openly profeffed, ferves to fhew, that the want of an eftablifhment is attended with no danger to the ftate. It is farther objected, that the ftate, by undertaking the care of religion, the truth and utility of which will, under providence, enfure its permanence, has taken upon itfelf a great, dangerous, and unneceffary burden; and from its jealoufy of fectaries, often deprives itfelf of the fervices of fome of its beft and moft able fubjects; and at fome times it has been induced to perfecute and deftroy them, becaufe if they were left free, and even fuffered to live, it was apprehended their principles might fpread to the rifk of the eftablifhment. To the national eftablifhment of our own country, the enlightened advocates of which abhor and difcountenance intolerance and perfecution, it has been objected, that it deprives the people of the choice of their own teachers and paftors; that it impofes fubfcription to creeds of doubtful evidence, and the obfervance of forms of queftionable utility, on its own minifters; that it renders the fupport of them burdenfome to thofe who avail themfelves of their labours, and to others who derive no benefit from them; and that it excludes by obnoxious ftatutes a confiderable clafs of loyal fubjects from offices which they are competent to difcharge, as well as emoluments and honours of which they have a right to participate. See DISSENTERS, SUBSCRIPTION, TEST, and TYTHES.

We now proceed to ftate the arguments that have been urged in favour of national eftablifhments of religion; and we fhall here avail ourfelves of the reafoning of an excellent writer, who has done ample juftice to the fubject, and who, at the fame time, has difcuffed it with a liberality and moderation, which have a tendency to conciliate thofe whofe fentiments may be different from his own. "A religious eftablifhment," he fays, "is no part of Chriftianity; it is only the means of inculcating it." It cannot be proved, that any form of church government has been laid down in the Chriftian, as it had been in the Jewifh fcriptures, with a view of fixing a conftitution for fucceeding ages; and which conftitution, confequently, the difciples of Chrift would, every where, and at all times, by the very law of their religion, be obliged to adopt. Certainly no command for this purpofe was delivered by Chrift himfelf; and though the apoftles ordained bifhops and prefbyters among their firft converts, and appointed alfo deacons and deaconeffes, invefting them with functions different from any that now fubfift, fuch offices were at firft erected in the Chriftian church, as the good order, the inftruction, and the exigencies of the fociety at that time required, without any declared defign of regulating the appointment, authority, or diftinction of Chriftian minifters under future circumftances. After this conceffion, our author founds the authority of a church eftablifhment in its utility; and in judging of the comparative excellence of different eftablifhments, he fuggefts, that the fingle view, under which we ought to confider any of them, is that of "a fcheme of inftruction," and the fingle end we ought to propofe by them is, "the prefervation and communication of religious knowledge." Every other idea, and every other end that have been mixed with this, as the making of the church an engine, or even an ally of the ftate; converting it into the means of ftrengthening, or of diffufing influence; or regarding it as a fupport of regal, in oppofition to popular forms of government, have ferved only

to

to debafe the inftitution, and to introduce into it numerous corruptions and abufes. The notion, fays our author, of a religious eftablifhment comprehends three things, a clergy, or order of men fecluded from other profeffions to attend upon the offices of religion; a legal provifion for the maintenance of the clergy: and the confining of that provifion to the teachers of a particular fect of Chriftians. Without thefe, there exifts no national religion, or eftablifhed church, according to the fenfe which thefe terms are ufually made to convey. He, therefore, who would defend ecclefiaftical eftablifhments, muft fhew the feparate utility of thefe three effential parts of their conftitution. Under the firft head he maintains, that the knowledge and profeffion of Chriftianity cannot be maintained in a country without a clafs of men fet apart by public authority to the ftudy and teaching of religion, and to the conducting of public worfhip; and that for thefe purpofes they fhould be precluded from other employments; and that of courfe they ought to derive a maintenance from their own. If they depended for this maintenance upon the voluntary contributions of their hearers, he is of opinion, that few would ultimately contribute any thing at all. To the confideration of the difficulty with which congregations would be eftablifhed and upheld upon the *voluntary* plan, he adds, that of the condition of thofe who are to officiate in them. Preaching, he thinks, would in this cafe become a kind of begging; and the preacher, being at the mercy of his audience, would be obliged to adapt his doctrines, and alfo his ftyle and manner of preaching, to the pleafure of a capricious multitude; and to live in conftant bondage to tyrannical and infolent directors; which he could not do without a facrifice of principle, and a depravation of character. Admitting thefe circumftances to be fairly ftated, which perhaps an objector would reluctantly allow. Dr. Paley concludes, that a legal provifion for the clergy, compulfory upon thofe who contribute to it, is expedient; and then proceeds to inquire, whether this provifion fhould be confined to one fect of Chriftians, or extended indifferently to all. This queftion, it fhould be recollected, *can* never offer itfelf where the people are agreed in their religious opinions, and *ought* never to arife, where a fyftem of doctrines and worfhip may be fo framed as to comprehend their difagreements, and which might fatisfy all by uniting all in the articles of their common faith, and in a mode of divine worfhip that omits every fubject of controverfy or offence. Where fuch a comprehenfion is practicable, the comprehending religion ought to be made that of the ftate. But where this comprehenfion is impracticable, and feparate congregations and different fects muft continue in the country, the queftion fairly recurs, whether, under fuch circumftances, the laws ought to eftablifh one fect in preference to the reft; that is, whether they ought to confer the provifion affigned to the maintenance of religion upon the teachers of one fyftem of doctrines alone. This queftion is intimately connected with, and in a great meafure dependent upon, another; and that is, in what way, or by whom, ought the minifters of religion to be *appointed?* In that fpecies of patronage which fubfifts in this country, and which allows private individuals to nominate teachers of religion for diftricts and congregations, to which they are abfolute ftrangers, fome teft fhould be propofed to the perfons nominated, in order to prevent that difcordancy of religious opinions that might otherwife arife between the feveral teachers and their refpective congregations. The requifition of fubfcription, or any other teft by which the national religion is guarded, may be confidered merely as a reftriction upon the exercife of private patronage. Wherefoever, therefore, this conftitution of patronage is adopted, a national religion, or the legal preference of one particular religion to all others, muft almoft neceffarily accompany it. If we fuppofe that the appointment of the minifter of religion was in every parifh left to the choice of the parifhioners, might not this choice be fafely exercifed, without its being limited to the teachers of any particular fect? The effect, fays our author, of fuch a liberty muft be, that a Papift, or a Prefbyterian, a Methodift, a Moravian, or an Anabaptift, would fucceffively gain poffeffion of the pulpit, according as a majority of the party happened at each election to prevail; and on every choice, it is apprehended, that violent conflicts would be renewed, and bitter animofities be revived. If the ftate appoint the minifters of religion, this conftitution will differ little from the eftablifhment of a national religion: for the ftate would undoubtedly appoint only thofe whofe religious opinions, or rather whofe religious denomination, agree with its own; unlefs it be thought that religious liberty would derive any advantage from transferring the choice of the national religion from the legiflature of the country to the magiftrate who adminifters the executive government. The only plan which feems to render the legal maintenance of a clergy practicable, without the legal preference of one fect of Chriftians to another, is that of an experiment which has been attempted (and which is faid to have fucceeded) in fome of the new ftates of North America. The nature of the plan is thus defcribed. A tax is levied upon the inhabitants for the general fupport of religion: the collector of the tax goes round with a regifter in his hand, in which are inferted, at the head of fo many diftinct columns, the names of the feveral religious fects that are profeffed in the country. The perfon who is called upon for the affeffment, as foon as he has paid his quota, fubfcribes his name in which of the columns he pleafes; and the amount of what is collected in each column is paid over to the minifter of that denomination. In this fcheme it is not left to the option of the fubject, whether he will contribute, or how much he fhall contribute, to the maintenance of a Chriftian minifter: it is only referred to his choice to determine by what fect his contribution fhall be received. The above arrangement, fays Paley, is undoubtedly the beft that has been propofed upon this principle; it bears the appearance of liberality and juftice; and it may contain fome folid advantages. But our author thinks that its inconveniences will be found to overbalance all its recommendations. It is fcarcely compatible with the firft requifite in an ecclefiaftical eftablifhment, which is the divifion of the country into parifhes of a commodious extent. If the parifhes be fmall, and minifters of every denomination be ftationed in each, which the plan feems to fuppofe, the expence of their maintenance will become too burdenfome a charge for the country to fupport. If, for reducing the expence, the diftricts be enlarged, the place of affembling will, in fome cafes, be too far removed from the refidence of the perfons who ought to refort to it. Befides, if the pecuniary fuccefs of the different teachers of religion be made to depend upon the number and wealth of their refpective followers, this would naturally generate ftrifes and indecent jealoufies amongft them, as well as produce a polemical and profelyting fpirit, founded in or mixed with views of private gain; which would both deprave the principles of the clergy, and diftract the country with endlefs contentions.

If it be expedient, fays our author, to eftablifh a national religion, that is, one fect in preference to all others, fome *teft*, by which the teacher of that fect may be diftinguifhed from the teachers of different fects, appears to be an indifpenfable confequence. The exiftence of fuch an eftablifhment

ment ſuppoſes it: the very notion of a national religion includes that of a teſt. But the neceſſity of a teſt has furniſhed to almoſt every church a pretence for extending, multiplying, and continuing ſuch teſts beyond what the occaſion juſtified. For though ſome purpoſes of order and tranquillity may be anſwered by the eſtabliſhment of creeds and confeſſions, yet they are at all times attended with ſerious inconveniences. They check inquiry; they violate liberty; they enſnare the conſciences of the clergy, by holding out temptations to prevarication; and in proceſs of time, they contradict the opinions of the church, whoſe doctrines they profeſs to contain; and they often perpetuate the proſcription of ſects and tenets, from which any danger has long ceaſed to be apprehended. Although teſts and ſubſcriptions may not be aboliſhed, they ſhould be made as eaſy and ſimple as poſſible. They ſhould be adapted from time to time to the varying ſentiments and circumſtances of the church in which they are received; nor ſhould they at any time advance one ſtep farther than ſome ſubſiſting neceſſity requires. Promiſes of conformity to the rites, liturgy, and offices of the church, if ſufficient to prevent confuſion in the celebration of divine worſhip, ſhould be accepted in the place of ſtricter ſubſcriptions. If any agreements, not to preach certain doctrines, nor to revive certain controverſies, denominated articles of *peace*, would exclude indecent altercations amongſt the national clergy, and alſo ſecure to the public teaching of religion as much of uniformity and quiet as is neceſſary to edification; then confeſſions of faith ought to be converted into articles of peace. In a word, it ought to be held, ſays Dr. Paley, a ſufficient reaſon for relaxing the terms of ſubſcription, or for dropping any or all of the articles to be ſubſcribed, that no preſent neceſſity requires greater ſtrictneſs.

It is a queſtion that has been long agitated in the reformed churches of Chriſtendom, whether a parity amongſt the clergy, or a diſtinction of orders in the miniſtry, be more conducive to the general ends of the inſtitution? Our author is inclined to the latter alternative, for reaſons which he has ſtated.

In diſcuſſing the ſubject of a national eſtabliſhment of religion, the right of the civil magiſtrate to interfere at all in matters of religion offers itſelf to conſideration; and although this right may be acknowledged whilſt he is employed ſolely in providing means of public inſtruction, it may be queſtioned whether he ſhould inflict penalties, and impoſe reſtraints or incapacities on the account of religious diſtinctions. Our author, deducing the authority of civil government from the will of God, and inferring that will from public expediency alone, concludes that the juriſdiction of the magiſtrate is limited by no conſideration but that of general utility; or that whatever be the ſubject demanding regulation, it is lawful for him to interfere, whenever his interference, in its general tendency, appears to be conducive to the common intereſt. Our author conceives, that there is nothing in the nature of religion, as *ſuch*, which exempts it from the authority of the legiſlator, when the ſafety or welfare of the community requires his interpoſition. To the objection, that religion, pertaining to the intereſts of a life to come, lies beyond the province of the civil government, the office of which is confined to the affairs of this life, Dr. Paley replies, that when the laws interfere even in religion, they interfere only with temporals; their effects terminate, their power operates only upon thoſe rights and intereſts, which confeſſedly belong to their diſpoſal. He proceeds to obſerve, probably without ſatisfying the objector, "that the acts of the legiſlator, the edicts of the prince, the ſentence of the judge, cannot affect my ſalvation; nor do they, without the moſt abſurd arrogance, pretend to any ſuch power: but they may deprive me of liberty, property, and even of life itſelf, on account of my religion; and however I may complain of the injuſtice of the ſentence, by which I am condemned, I cannot allege that the magiſtrate has tranſgreſſed the boundaries of his juriſdiction; becauſe the property, the liberty, and the life of the ſubject, may be taken away by the authority of the laws, for any reaſon, which, in the judgment of the legiſlature, renders ſuch a meaſure neceſſary to the common welfare. Moreover, as the precepts of religion may regulate all the offices of life, or may be ſo conſtrued as to extend to all, the exemption of religion from the control of human laws might afford a plea, which would exclude civil government from every authority over the conduct of its ſubjects. Religious liberty is like civil liberty, not an immunity from reſtraint, but the being reſtrained by no law, but what in a greater degree conduces to the public welfare."

By way of qualifying this reaſoning, which may be thought exceptionable, Dr. Paley obſerves, that "ſtill it is right to obey God rather than man."—"When human laws interpoſe their direction in matters of religion, by dictating, for example, the object or the mode of divine worſhip; by prohibiting the profeſſion of ſome articles of faith, and by exacting that of others; they are liable to claſh with what private perſons believe to be already ſettled by precepts of revelation, or to contradict what God himſelf, they think, hath declared to be true. In this caſe, on whichever ſide the miſtake lies, or whatever plea the ſtate may allege to juſtify its edict, the ſubject can have none to excuſe his compliance. The ſame conſideration alſo points out the diſtinction, as to the authority of the ſtate between temporals and ſpirituals. The magiſtate is not to be obeyed in temporals more than in ſpirituals, where a repugnance is perceived between his commands, and any credited manifeſtations of the divine will; but ſuch repugnancies are much leſs likely to ariſe in one caſe than in the other." The general propoſition laid down by our author is as follows: "That it is lawful for the magiſtrate to interfere in the affairs of religion, whenever his interference appears to him to conduce, by its general tendency, to the public happineſs." To others this propoſition will appear to be in many reſpects exceptionable. The magiſtrate of courſe is to be the judge, what are the occaſions in which he may interfere; and theſe occaſions will occur whenever he pleaſes. Dr. Paley has therefore endeavoured to guard it againſt miſapprehenſion and miſapplication. Having ſtated, that it is the *general* tendency of the meaſure, or, in other words, the effects which would ariſe from the meaſure being *generally* adopted, that fixes upon it the character of rectitude or injuſtice, he then proceeds to inquire what is the degree and the ſort of interference of ſecular laws in matters of religion, which are likely to be beneficial to the public happineſs. In ſettling this point he premiſes two maxims; the firſt is, that any form of Chriſtianity is better than no religion at all; and the ſecond is, that of different ſyſtems of faith, that is the beſt which is the trueſt. From the firſt propoſition it is inferred, that when the ſtate enables its ſubjects to learn *ſome* form of Chriſtianity by diſtributing teachers of a religious ſyſtem throughout the country, and by providing for the maintenance of theſe teachers at the public expence; that is, when the *laws* eſtabliſh a national religion, they exerciſe a power and interference, which are likely, in their general tendency, to promote the intereſt of mankind.

But after the right of the magiſtrate to eſtabliſh a particular religion has been, upon this principle, admitted; a doubt ariſes, whether the religion he ought to eſtabliſh be that which he himſelf profeſſes, or that which he obſerves to prevail amongſt the majority of the people. Aſſuming it to be an equal chance, which of the two religions, that of the magiſtrate or that of the people, contains more of truth, it becomes a conſideration of ſome importance, to which arrangement we may attach the greater efficacy; that of an order of men appointed to teach the people their own religion, or to convert them to another; and as in our author's opinion the advantage lies on the ſide of the former ſcheme, it becomes the duty of the magiſtrate, in the choice of the religion which he eſtabliſhes, to conſult the faith of the nation rather than his own. For our author's reaſoning on other topics connected with a national eſtabliſhment of religion, we refer to the articles Subscription, Test, and Toleration. He cloſes the diſcuſſion of the general ſubject with the following ſummary of his argument: the reſult of our examination of thoſe general tendencies, by which every interference of civil government in matters of religion ought to be tried, is this: "That a comprehenſive national religion, guarded by a few articles of peace, and conformity, together with a legal proviſion for the clergy of that religion; and with a *complete* toleration of all diſſenters from the eſtabliſhed church, without any other limitation or exception, than what ariſes from the conjunction of dangerous political diſpoſitions with certain religious tenets, appears to be, not only the moſt juſt and liberal, but the wiſeſt and ſafeſt ſyſtem, which a ſtate can adopt: inaſmuch as it unites the ſeveral perfections, which a religious conſtitution ought to aim at—liberty of conſcience, with means of inſtruction; the progreſs of truth, with the peace of ſociety; the right of private judgment, with the care of the public ſafety." Paley's Principles of Moral and Political Philoſophy, vol. ii. ch. 10.

In moſt countries where religion is eſtabliſhed, it is that of the majority of the people; and on this principle the writers in defence of eccleſiaſtical eſtabliſhments vindicate them. But in a part of the united kingdom of Great Britain, *viz.* in Ireland, we have a remarkable exception to this rule. There the eſtabliſhed religion is not that of the majority, but of a ſmall minority of the people. Ever ſince the reformation the members of the church of England have kept poſſeſſion of the tithes of the whole iſland, where they have long deſpaired of bringing the people over to that religion for which they pay ſo dear.

In connection with the national eſtabliſhment of religion we ſhall here remark, that in this country the care which government takes of religion extends itſelf to the buſineſs of *education*, confining the univerſities, which are ſupported by the national funds, to the education of the members of the church of England, and rigorouſly excluding all ſectaries, either by requiring ſubſcription to the thirty-nine articles at the time of matriculation, or of taking certain degrees, or obliging the ſtudents to attend the ſervice of the eſtabliſhed church, and to declare that they are *bona fide* members of it.

Among the offences againſt religion enumerated by judge Blackſtone, and puniſhable by the laws of England, are *apoſtacy* and *hereſy*, which ſee reſpectively; and alſo thoſe which affect the eſtabliſhed church. Theſe latter are either poſitive or negative; poſitive by reviling its ordinances, or negative, by non-conformity to its worſhip. See Reviling, &c. Common *Prayer*, Non-conformists, Dissenters, Papists, and Popery. See alſo Blasphemy, Profaneness, Conjuration and Witchcraft, *Religious* Impostors, Sunday, *Falſe* Prophecies, Drunkenness, Lewdness, and Simony.

Religion, again, is applied to a military order, conſiſting of knights who live under ſome certain rule, &c.

In this ſenſe we ſay, the *religion of Malta*, &c. See Malta.

Religion is ſometimes alſo uſed for a convent. Thus, we ſay, there are religions of men, *i. e.* monks; religions of women, *i. e.* nuns.

Religion, *The*, uſed abſolutely, denotes the Reformed in France. Thus, they ſay, d'Ablancourt and Dacier were of the religion. See Huguenots.

RELIGIOUS, in a general ſenſe, ſomething that relates to religion.

We ſay, a religious life, religious ſociety, &c. Churches and church-yards are religious places. A religious war is alſo called a *croiſade;* which ſee.

Religious is more particularly uſed for a perſon engaged by ſolemn vows to the monaſtic life; or a perſon ſhut up in a monaſtery, to lead a life of devotion and auſterity, under ſome rule or inſtitution.

The male religious we popularly call *monks* and *friars;* the female, *nuns* and *canoneſſes*. See Canon, Monk, Nun, &c.

M. Nicole obſerves, that ſome domeſtic chagrins, and a certain pride, which leads people to abſcond when they cannot make a figure to their mind, make as many religious as real piety. He adds, that a girl muſt often be made a religious for no other reaſon, but becauſe ſhe cannot be married anſwerable to her condition.

Great influence, however, may be attributed to enthuſiaſm and ſuperſtition, and to thoſe miſtaken notions of duty and of perfection of character, which have often originated in theſe ſources, and which have produced effect on honeſt minds of a peculiar temperament and diſpoſition. Whilſt no kind of argument can juſtify this retirement from the world, and total ſecluſion from the occupations and pleaſures of ſocial life, it would manifeſt a want of candour as well as ignorance of human nature indiſcriminately to condemn all who have devoted themſelves to ſuch a kind of indolent and uſeleſs life.

A religious cannot make any will. By the council of Trent, a religious may reclaim his vows within five years.

Anciently the religious were all laymen, and it was even prohibited them to take up orders. In 1557, the parliament of Paris made a difficulty of receiving a biſhop of Laon to the oath of a duke and peer, by reaſon of his being a religious: yet a religious, being promoted to a biſhopric, is thenceforth ſecularized or diſpenſed from the obſervation of his rule.

In ancient deeds and conveyances of lands, we often find the ſeller reſtrained from giving or alienating it, *viris religioſis, vel Judæis*, to religious, or to Jews; to the end the land might not fall into *mortmain;* which ſee.

In a memorial directed by king John to his viſcounts, they are ordered to proclaim through their reſpective counties, that nobody, as they love their bodies and cattle, injure the religious or clerks, either in word or deed, on penalty of being hanged up on the next oak. "Nulli, ſicut diligunt corpora et catalla ſua, malum faciant vel dicant viris religioſis vel clericis. Si quem inde attingere poſſimus, ad proximam quercum eum ſuſpendi faciemus."

Religious *Houſes*, denote houſes ſet apart for religious purpoſes,

purposes, such as monasteries, churches, hospitals, and all other places where charity is extended to the relief of the poor and orphans, or for the use or exercise of religion. See "Notitia Monastica," or "A short History of the religious Houses in England and Wales," by Tanner, 8vo.; in which, according to the alphabetical order of counties, is accurately given a full account of the founders, the time of foundation, tutelar saints, the order, the value, and the dissolution; with reference to printed authors and MSS. which preserve any memoirs relating to each house; with a preface of the institution of religious orders. Cowel.

Religious *Impostors*. See Impostors.

Religious *Order*. See Order.

Most military orders pretend likewise to be religious; as those of Malta, who make vows, &c. See Malta.

RELINQUISHMENT, in *Law*, is a forsaking, abandoning, or giving over. It hath been adjudged, that a person may relinquish an ill demand in a declaration, &c. and have judgment for that which is well-demanded.

RELIQUA, the remainder or debt, which a person finds himself debtor in, upon the balancing or liquidating an account.

Hence *reliquitary*, the debtor of a reliqua; as also a person who only pays piece-meal.

The term reliqua is pure Latin.

RELIQUÆ, Relics, in *Antiquity*, the ashes and bones of the dead, which remained after burning their bodies; and which they very religiously gathered, and put into urns, and afterwards deposited in tombs. See Relics.

RELIQUARY, a shrine or casket, in which the relics of a dead saint are kept.

RELIQUE. See Relics.

RELIQUIA, in *Natural History*, a term used to express the fossile remains of certain substances found in different parts of the earth. In the article Petrifactions we have given the Linnæan division of the fifth class of minerals, and a pretty full description of the eight genera into which it is divided. In this place we shall present our readers with a very brief view of Mr. Martin's "Systema Reliquiorum." He considers the regnum fossile, or fossile kingdom, to be divided into five classes, *viz.*

I. Reliquia, or fossile remains from animals or plants.
II. Terræ, earths.
III. Salia, salts.
IV. Inflammabilia, inflammable substances.
V. Metalla, metallic substances.

The reliquia he divides into two orders, *viz. animal* and *vegetable* remains: of the former he gives eight genera; of the latter only one genus, which are as follow:

Order I. Reliquia Animalia.

Innata.

Genus 1. Mammodolithus, or remains of Mammalia.
2. Ornitholithus, - - Birds.
3. Amphibiolithus, - - Amphibia.
4. Ichthyolithus, - - Fishes.
5. Entholithus, - - Insects.
6. Helmintholithus, of the parts of worms not fabricated.

Fabricata.

7. Conchyliothus, or remains of Testacea.
8. Erismatolithus, of fulciments, or fabricated supports of worms.

Order II. Reliquia Vegetalia.

9. Phytolithus, the remains of Plants.

Mr. Martin has given certain fundamental principles, on which he conceives the study of reliquia may be scientifically conducted: these are as follow.

1. All natural bodies without life found on or beneath the surface of the earth, and which are not susceptible of putrefaction, belong to the fossile kingdom, and are either reliquia or minerals. Fossils are usually denominated "bodies destitute of an organic structure:" now though it be admitted that all fossils are, according to the common acceptation of the term, unorganized, they are not destitute of the structure which distinguishes an organized body. This being admitted, it follows that a line must be drawn between animal and vegetable matter recently buried in the earth, and which has acquired a genuine fossile character. This line will depend perhaps on putrefaction, to which even organic substances, after they have become fossile, are no longer subject.

2. An organic structure, whether of a plant or animal, is the essence of an extraneous fossil or reliquium. By this alone it is characterised, or distinguished from a mineral.

3. It is the organic form alone on which the arrangement of reliquia must be founded. Every system of natural bodies should assume for its basis but one principle, and this should be drawn from the most essential characteristics of the bodies under arrangement. It is on this account the form is pointed out as furnishing the only genuine principle, on which the classification of reliquia can be established.

4. The primary divisions of the arrangement, *viz.* orders, genera, &c. should agree with such natural divisions of plants and animals as are determinable by the form of the fossile subjects.

5. The specific differences in reliquia depend on the specific differences of form in the original bodies. One species of plant or animal can give but one real or genuine species of extraneous fossil. For if the essence of the reliquium be an organic form, its other affections, arising from substance, mode, and soil, are accidental, and cannot be used as specific distinctions, which must always depend on something essential to the body which we wish to discriminate. *Form*, therefore, must furnish specific differences of reliquia, and it of course follows that there will be as many genuine species of reliquia, as there are genuine specific forms in the animal and vegetable prototypes or originals: and that the number of fossile species are not increased by a separation of parts, or other accidental circumstances to which the original bodies may have been subjected during their change into fossils.

6. Specific distinctions of reliquia being founded only on the organic form, it follows, that their geological and mineralogical affections, with their modal diversities, merely characterise specimens.

7. The specific descriptions of reliquia are to be given according to the principles of botany and zoology. Those of the specimens, according to the principles of mineralogy and geology. The *essential* form of the reliquium must be distinguished from the *accidental*, that is, the form of the original body, from that which has arisen in the fossil from the mode of mineralization, the constituent substance, and the soil of the specimen.

8. The nomenclature of reliquia should manifest the extent of the present state of knowledge with respect to the original bodies.

To what has been said, we shall add an account of our author's "Delineations of Reliquia."

The leading parts in the delineation of a reliquium are the

the ſpecific character or diagnoſis, and the general deſcription.

The *ſpecific character* contains the marks that diſtinguiſh the ſpecies to which they belong, from all others in the ſame genus. Specific characters of reliquia ſhould be ſo conſtructed as to diſtinguiſh permanent from temporary ſpecies; and thoſe whoſe originals have not, as yet, been diſcovered. The ſpecific character of the recent ſpecies of plants or animals frequently depends on parts often or conſtantly wanting in the foſſile ſubject. When that is the caſe, another diagnoſis muſt be given to diſtinguiſh the reliquium; that of the recent ſpecies being marked as a parentheſis. The generic and trivial names are prefixed to the ſpecific character. And, generally, the name of the family, or ſubdiviſion of the genus to which the reliquium belongs: after which is to be detailed in diſtinct claſſes, 1. The ſynonyms or names by which the ſpecies has been diſtinguiſhed by authors, with references to the figures given of it. 2. The varieties of the ſpecies, with their ſynonyms. 3. The vernacular name. 4. The mode or ſtate in which the reliquium is found. 5. Its ſoil or geological ſituation. 6. Its geographic ſituation, and then the general deſcription.

The deſcription delineates in appropriate terms all the parts conſtituting the eſſential form of the reliquium, according to their number, figure, proportion, and ſituation: it muſt primarily refer to the original of the reliquium, as no juſt or perfect delineation of the ſpecies can be given, until the nature of its prototype be aſcertained.

The terms employed in deſcribing reliquia, which derive their form from the external parts of animals and plants, muſt be thoſe uſed by zoologiſts and botaniſts of the Linnæan ſchool. But thoſe which derive their form from the internal parts of organic bodies, are to be deſcribed in ſuch terms as anatomiſts would uſe in diſtinguiſhing the ſame parts in the recent ſubjects.

As appendant parts to the general deſcription of the reliquium muſt be given, 1. An enumeration of the ſpecimens which exhibit the various accidental forms under which the ſpecies has been found. 2. An enumeration of the various ſubſtances which have been obſerved as conſtituting the reliquium and its matrix.

Having given this brief account of Mr. Martin's ſcientific delineations of reliquia, we ſhall preſent our readers with the ſubſtance of two very intereſting communications ſent to the Royal Society ſince the printing of the article PETRIFACTIONS. Of theſe, the firſt is "An Account of ſome Organic Remains found by Mr. Trimmer, near Brentford, in Middleſex."

"The ſpecimens," ſays Mr. Trimmer, "have been collected from two fields, not contiguous to each other; therefore, to avoid confuſion, I ſhall take each field ſeparately, firſt deſcribing the ſtrata as far as they have come within my knowledge, and afterwards I ſhall ſpeak of the organic remains as they were reſpectively found in thoſe ſtrata.

"The firſt field is about half a mile north of the Thames at Kew bridge; its ſurface is about twenty-five feet above the Thames at low water. The ſtrata here are, firſt, ſandy loam from ſix to ſeven feet, the loweſt two feet ſlightly calcareous. Second, ſandy gravel, a few inches only in thickneſs. Third, loam ſlightly calcareous, from one to five feet: between this and the next ſtratum, peat frequently intervenes in ſmall patches, of only a few yards wide, and a few inches thick. Fourth, gravel containing water; this ſtratum varies from two to ten feet in thickneſs, and is always the deepeſt in the places covered by peat; in theſe places the lower part of the ſtratum becomes an heterogeneous maſs of clay, ſand, and gravel, and frequently exhales a diſagreeable muddy ſmell. Fifth, the main ſtratum of blue clay, which lies under this, extends under London and its vicinity; the average depth of this clay has been aſcertained, by wells that have been dug through it, to be about two hundred feet under the ſurface of the more level lands, and proportionally deeper under the hills, as appears from lord Spencer's well at Wimbledon, which is five hundred and ſixty-ſeven feet deep. This ſtratum, beſides figured foſſils, contains pyrites and many detached nodules; at the depth of twenty feet there is a regular ſtratum of theſe nodules, ſome of which are of very conſiderable ſize.

"In the firſt ſtratum, as far as my obſervation has extended, no remains of an organized body has ever been found, and as my ſearch has not been very limited, I may venture to ſay it contains none. In the ſecond ſtratum, ſnail-ſhells, and the ſhells of river-fiſh, have been found, and a few bones of land animals, but of inconſiderable ſize, and in ſuch a mutilated ſtate, that it cannot be aſcertained to what claſs they belong. In the third ſtratum, the horns and bones of the ox, and the horns, bones, and teeth of the deer, have been found, and alſo, as in the ſecond ſtratum, ſnail-ſhells, and the ſhells of river-fiſh. In the fourth ſtratum were found teeth and bones of both the African and Aſiatic elephants, teeth of the hippopotamus, bones, horns, and teeth of the ox.

"A tuſk of an elephant meaſured, as it lay on the ground, nine feet three inches, but, in attempting to remove it, it broke into ſmall pieces. When this ſtratum dips into the clay, and becomes a mixed maſs, as before ſtated, it is ſeldom without the remains of animals. In the fifth ſtratum, namely, the blue clay, the extraneous foſſils are entirely marine, with the exception of ſome ſpecimens of fruit and pieces of petrified wood, the latter of which may be conſidered as marine, becauſe, when of ſufficient ſize, they are always penetrated by teredines. The other foſſils from this ſtratum are nautili, oyſters, pinnæ marinæ, crabs, teeth and bones of fiſh, and a great variety of ſmall marine ſhells; this ſtratum has been penetrated hitherto in this field only to the depth of thirty feet, throughout which the ſpecimens found were diſperſed without any regularity.

"The ſecond field is about one mile to the weſtward of the former, one mile north of the Thames, and a quarter of a mile to the eaſtward of the river Brent; its height above the Thames, at low water, is about forty feet. The ſtrata are, firſt, ſandy loam, eight or nine feet, in the loweſt three feet of which it is ſlightly calcareous. Second, ſand, becoming coarſer towards the loweſt part, and ending in ſandy gravel from three to eight feet. Third, ſandy loam highly calcareous, having its upper ſurface nearly level, but gradually increaſing in thickneſs from a feather-edge to nine feet. Below this are two ſtrata of gravel and clay, as in the other field; but as theſe ſtrata have been only occaſionally penetrated in digging for water, nothing therefore is known with reſpect to them, but that they exiſt there.

"In the firſt ſtratum, as in the other field, no organic remains have been obſerved. In the ſecond, but always within two feet of the third ſtratum, have been found the teeth and bones of the hippopotamus, the teeth and bones of the elephant, the horns, bones and teeth of ſeveral ſpecies of deer, the horns, bones and teeth of the ox, and the ſhells of river-fiſh.

"The remains of hippopotami are ſo extremely abundant, that, in turning over an area of 120 yards in the preſent ſeaſon, parts of ſix tuſks have been found of this animal, beſides a tooth and part of the horn of a deer, part of a tuſk, and part of a grinder of an elephant, and the horns, with a ſmall part of the ſkull, of an ox. One of theſe horns I had an opportunity of meafuring as it lay on the ground, and found it to be $4\frac{1}{2}$ feet in length, and five inches in diameter at the large end; it was found impracticable to remove it, otherwife than in fragments, which I have preferved, and have hopes of being able to put a confiderable part of it together. The immenfe fize of this horn is rendered more remarkable by another horn from the fame fpot, which meafures but fix inches in length. Though this ftratum is fo extremely productive of the remains of animals, yet there are but few good cabinet fpecimens from it, owing, it is prefumed, to their having been crufhed at the time they were buried, and to the injury they have fince received from moifture. It is neceffary to remark, that the gravel-ftones in this ftratum do not appear to have been rounded in the ufual way by attrition, and that the bones muft have been depofited after the flefh was off, becaufe, in no inftance, have two bones been found together which were joined in the living animal; and further, that the bones are not in the leaft worn, as muft have been the cafe had they been expofed to the wafh of a fea-beach.

"In the third ftratum, *viz.* calcareous loam, have been found the horns, bones and teeth of the deer, the bones and teeth of the ox, together with fnail-fhells, and the fhells of river-fifh.

"Brentford, in the neighbourhood of which are the fields I have mentioned, is fituated on the north bank of the Thames, and is fix miles weft of London.

"The fall of the Thames from Brentford to its mouth at the Nore, is eftimated at feven feet."

The next communication is in relation to a foffile human fkeleton, found imbedded in lime-ftone lately brought from the ifland of Guadaloupe by the honourable fir Alexander Cochrane, and prefented by the admiralty to the Britifh Mufeum. Of this highly curious fpecimen Mr. Konig has given an account that, to naturalifts, will be regarded as highly important and interefting.

"On the hiftory of the ftrata produced by the more recent cataftrophes of the globe," fays Mr. Konig, "moft light has been thrown by the indefatigable exertions of M. Cuvier. Superlatively fkilled in comparative anatomy, this gentleman has fucceeded in determining the foffile bones of no lefs than 78 fpecies, of which 49 are entirely unknown among the exifting races of animals; about 12 are identified with known fpecies, and the remainder ftrongly refemble exifting fpecies, although their identity has not been completely afcertained. From the multiplied obfervations which this naturalift has communicated in his numerous memoirs, we may gather that the viviparous quadrupeds appear at a much later period in the foffile ftate than the oviparous; the latter being probably coeval with the fifhes, whilft the former are found only in the neweft formations, in which, according to Brongniart and Cuvier's interefting difcovery, marine beds are obferved to alternate with thofe of frefh water, and which (in the neighbourhood of Paris) overlay the coarfe fhell lime-ftone, which conftitutes the laft ftrata formed, as it would appear, by a long and quiet ftay of the fea on our continent.

"All the circumftances under which the known depofitions of bones occur, both in alluvial beds and in the caverns and fiffures of flœtz lime-ftone, tend to prove, that the animals to which they belonged met their fate in the very places where they now lie buried. Hence, it may be confidered as an axiom, that man, and other animals, whofe bones are not found intermixed with them, did not co-exift in time and place. The fame mode of reafoning would further juftify us in the conclufion, that, if thofe cataftrophes which overwhelmed a great proportion of the brute creation were general, as geognoftic obfervations in various parts of the world render probable, the creation of man muft have been pofterior to that of thofe genera and fpecies of mammalia which perifhed by a general cataclyfm, and whofe bones are fo thickly diffeminated in the more recent formations of rocks.

"The human fkeletons from Guadaloupe are called Galibi by the natives of that ifland; a name faid to have been that of an ancient tribe of Caribs of Guiana, but which, according to a plaufible conjecture, originated in the fubftitution of the letter *l* inftead of *r*, in the word Caribbee. No mention is made of them by any author except general Ernouf, in a letter to M. Faujas St. Fond, inferted in vol. v. (1805) of the Annales du Mufćum; and by M. Lavaiffe, in his Voyage à la Trinidad, &c. publifhed in 1813. The former of thefe gentlemen writes, that, on that part of the windward fide of the Grande-Terre, called La Moule, fkeletons are found enveloped in what he terms "Maffes de madrépores pétrifiés," which being very hard, and fituated within the line of high water, could not be worked without great difficulty, but that he expected to fucceed in caufing fome of thefe maffes to be detached, the meafurements of which he ftates to be about eight feet by two and a half.

"The block brought home by fir Alexander Cochrane exactly anfwered this account with regard to the meafurements; in thicknefs it was about a foot and a half. It weighed nearly two tons; its fhape was irregular, approaching to a flattened oval, with here and there fome concavities, the largeft of which, as it afterwards appeared, occupying the place where the thigh-bone had been fituated, the lower part of which was therefore wanting. Except the few holes evidently made to affift in raifing the block, the mafons here declared, that there was no mark of a tool upon any part of it; and, indeed, the whole had very much the appearance of a huge nodule difengaged from a furrounding mafs.

"The fituation of the fkeleton in the block was fo fuperficial, that its prefence in the rock on the coaft had probably been indicated by the projection of fome of the more elevated parts of the left fore-arm.

"The fkull is wanting; a circumftance which is the more to be regretted, as this characteriftic part might poffibly have thrown fome light on the fubject under confideration, or would, at leaft, have fettled the queftion, whether the fkeleton is that of a Carib, who ufed to give the frontal bone of the head a particular fhape by compreffion; which had the effect of depreffing the upper, and protruding the lower edge of the orbits, fo as to make the direction of their opening nearly upwards, or horizontal, inftead of vertical.

"The vertebræ of the neck were loft with the head. The bones of the thorax bear all the marks of confiderable concuffion, and are completely diflocated. The feven true ribs of the left fide, though their heads are not in connection with the vertebræ, are complete; but only three of the falfe ribs are obfervable. On the right fide only fragments of thefe bones are feen; but the upper part of the feven true ribs of this fide are found on the left, and might at firft fight be taken for the termination of the left ribs. The right ribs muft, therefore, have been violently broken, and carried over to the left fide, where, if this mode of viewing the fubject be correct, the fternum muft likewife lie concealed below the termination of the ribs. The fmall bone dependent above the upper ribs of the left fide, appears to be the right clavicle. The right os humeri is loft; of the left nothing remains except the condyles in connection with the fore-arm, which is in the ftate of pronation; the radius of this fide exifts nearly in its full length, while of the ulna the lower part only remains, which is confiderably pufhed upwards. Of the two bones of the right fore-arm, the inferior terminations

tions are seen. Both the rows of the bones of the wrists are lost, but the whole metacarpus of the left hand is displayed, together with part of the bones of the fingers: the first joint of the fore-finger rests on the upper ridge of the os pubis, the two others, detached from their metacarpal bones, are propelled downwards, and situated at the inner side of the femur, and below the foramen magnum ischii of this side. Vestiges of three of the fingers of the right hand are likewise visible, considerably below the lower portion of the fore-arm, and close to the upper extremity of the femur. The vertebræ may be traced along the whole length of the column, but are in no part of it well defined. Of the os sacrum, the superior portion only is distinct: it is disunited from the last vertebra and the ilium, and driven upwards. The left os ilium is nearly complete; but shattered, and one of the fragments depressed below the level of the rest: the ossa pubis, though well defined, are gradually lost in the mass of the stone. On the right side the os innominatum is completely shattered, and the fragments are sunk; but towards the acetabulum, part of its internal cellular structure is discernible.

"The thigh-bones and the bones of the leg of the right side are in good preservation, but being considerably turned outwards, the fibula lies buried in the stone, and is not seen. The lower part of the femur of this side is indicated only by a bony outline, and appears to have been distended by the compact lime-stone that fills the cavities both of the bones of the leg and thigh, and to the expansion of which these bones probably owe their present shattered condition. The lower end of the left thigh-bone appears to have been broken and lost in the operation of detaching the block; the two bones of the leg, however, on this side are nearly complete: the tibia was split almost the whole of its length a little below the external edge, and the fissure being filled up with lime-stone, now presents itself as a dark-coloured straight line. The portion of the stone which contained part of the bones of the tarsus and metatarsus was unfortunately broken; but the separate fragments are preserved.

"The whole of the bones, when first laid bare, had a mouldering appearance, and the hard surrounding stone could not be detached, without frequently injuring their surface; but, after an exposure for some days to the air, they acquired a considerable degree of hardness. Sir H. Davy, who subjected a small portion of them to chemical analysis, found that they contained part of their animal matter, and all their phosphate of lime. Here follows an exact description of the rock, in which the fossile skeleton is found. The attention of geologists being now directed towards this object, it may be expected that a scientific examination of the circumstances under which this lime-stone occurs, will not fail ere long to fix its age, and assign to it the place it is to occupy in the series of rocks. All our present information respecting the Grande Terre of Guadaloupe amounts to this, that it is a flat lime-stone country, derived principally from the detritus of zoophytes, with here and there single hills (mornes) composed of shell lime-stone; while Guadaloupe, properly so called, separated from the upper part by a narrow channel of the sea, has no traces of lime-stone, and is entirely volcanic."

M. Lavaisse, alluded to above as the only author who mentions the galibies, except general Ernouf, speaks of the bed of lime-stone which incloses them, as the most remarkable of the calcareous rocks in the Leeward islands. Mr. Konig, therefore, expected to find in his work an exact statement of its mode of occurring; but the only positive information he could collect from this author is, that the bed is a kilomètre (nearly an English mile) in length, and that it is covered by the sea at high water. According to him, no trace of shells or organized bodies is discoverable in this rock; but in lieu of these, he was fortunate enough to meet with mortars, pestles, hatchets, &c. of a basaltic or porphyritic rock, which, we are informed, were petrified (petrifiés). From this very vague account, we should not be induced to lay much stress upon the circumstance that the position of the skeletons is east-west, and that the spot must, therefore, have been a cemetery, which time and circumstances have transformed into a hard calcareous rock.

"I have to apologise for this long letter on a subject," concludes Mr. Konig, "which may turn out to be interesting only so far, as the human bones from Guadaloupe are unquestionably the only bones we are acquainted with that have ever been found imbedded in a hard stony mass, that does not appear to belong to common stalactitical calcareous depositions. This circumstance admits of being easily ascertained by a close inspection of the locality; and I am perfectly of opinion, that a comparison of the nature of the different varieties of shell-sand, with which the neighbourhood of the Caribbee islands abounds, would alone be sufficient to remove many doubts relative to the origin of the bed in question. The sand from thence, which I had an opportunity of seeing, was unlike that of which the stone is composed."

RELL, Mouse, in *Zoology*, the English name of the white-bellied mouse, with a blackish back and long body. See Myoxus and Glis.

RELLING, in *Geography*, a town of the duchy of Holstein; 2 miles S.S.E. of Pinnenberg.

RELLINGEN, a town of France, in the department of the Moselle, and chief place of a canton, in the district of Thionville. The place contains 602, and the canton 9046 inhabitants, on a territory of 212½ kiliometres, in 36 communes.

RELLINGHAUSEN, a town of Germany, lately belonging to the abbey of Corvey; 16 miles N.N.E. of Dusseldorf.

RELLINGHUSEN, a town of the duchy of Holstein; 9 miles E. of Itzehoa.

REMAGEN, in *Geography*, a town of France, in the department of the Rhine and Moselle, and chief place of a canton, in the district of Bonn. The place contains 790, and the canton 7801 inhabitants, in 37 communes.

REMAIGHIAN, a town of Persia, in the province of Laristan; 10 miles N.W. of Tarem.

REMAINDER, Remanentia, in *Law*, an estate limited to take effect and be enjoyed after another estate is determined. As if a man seised in fee-simple granteth lands to A for twenty years, and, after the determination of the said term, then to B and his heirs for ever: here A is tenant for years, remainder to B in fee. In the first place, an estate for years is created or carved out of the fee, and given to A; and the residue or remainder of it is given to B. But both these interests are in fact only one estate; the present term of years and the remainder afterwards, when added together, being equal only to one estate in fee. (Co. Litt. 143.) Thus, also, if land be granted to A for twenty years, and after the determination of the said term to B for life; and after the determination of B's estate for life, it being limited to C and his heirs for ever: this makes A tenant for years, with remainder to B for life, remainder over to C in fee. In this case also, the first estate, and both the remainders, for life and in fee, are one estate only. Hence it is easy to infer, that no remainder can be limited after the grant of an estate in fee-simple (Plowd. 29.

 Vaugh.

Vaugh. 269.); because this is the higheft and largeft eftate that a fubject is capable of enjoying; and he that is tenant in fee, hath in him the whole of the eftate: a remainder, therefore, which is only a portion, or refiduary part of the eftate, cannot be referved after the whole is difpofed of.

The rules that are laid down by law to be obferved in the creation of remainders, are as follow. 1. There muft neceffarily be fome particular eftate, precedent to the eftate in remainder; which particular eftate is faid to fupport the remainder. (Co. Litt. 49. Plowd. 25.) 2. The remainder muft commence or pafs out of the grantor, at the time of the creation of the particular eftate (Litt. § 671. Plowd. 25.): as where there is an eftate to A for life, with remainder to B in fee; here B's remainder in fee paffes from the grantor at the fame time that feifin is delivered to A of his life-eftate in poffeffion. And it is this which induces the neceffity at common law of livery of feifin being made on the particular eftate, whenever a freehold remainder is created. (Litt. § 60. Co. Litt. 49.) 3. The remainder muft veft in the grantee during the continuance of the particular eftate, or *eo inftanti* that it determines. (Plowd. 25. 1 Rep. 66.) As if A be tenant for life, remainder to B in tail: here B's remainder is vefted in him, at the creation of the particular eftate to A for life: or if A and B be tenants for their joint lives, remainder to the furvivor in fee; here, though during their joint lives the remainder is vefted in neither, yet on the death of either of them, the remainder vefts inftantly in the furvivor; whence both thefe are good remainders. But if an eftate be limited to A for life, remainder to the eldeft fon of B in tail, and A dies before B hath any fon; here the remainder will be void, for it did not veft in any one during the continuance, nor at the determination, of the particular eftate: and even fuppofing that B fhould afterwards have a fon, he fhall not take by this remainder; for, as it did not veft at or before the end of the particular eftate, it never can veft at all, but is gone for ever. (1 Rep. 138.) Hence remainders are either *vefted* or *contingent*. *Vefted* remainders (or remainders executed, by which a prefent intereft paffes to the party, though to be enjoyed *in futuro*) are fuch where the eftate is invariably fixed, to remain to a determinate perfon after the particular eftate is fpent. As if A be tenant for twenty years, remainder to B in fee; here B's is a *vefted* remainder, which nothing can defeat or fet afide. *Contingent* or executory remainders (by which no prefent intereft paffes) are where the eftate in remainder is limited to take effect, either to a dubious and uncertain perfon, or upon a dubious or uncertain event; fo that the particular eftate may chance to be determined, and the remainder never take effect. (3 Rep. 20.) In the firft cafe, if A be tenant for life, with remainder to B's eldeft fon (then unborn) in tail, this is a contingent remainder, becaufe it is uncertain whether B will have a fon or not; and if A dies before B's fon is born, the remainder is abfolutely gone; even though A leaves his wife big with child, and after his death a pofthumous fon is born. (Salk. 228. 4 Mod. 282.) But to remedy this hardfhip, it is enacted by ftatute 10 & 11 W. III. cap. 16. that pofthumous children fhall be capable of taking in remainder, in the fame manner as if they had been born in their father's life-time; that is, the remainder is allowed to veft in them, while yet in their mother's womb. This fpecies of contingent remainder, to a perfon not in being, muft, however, be limited to fome one, that may by common poffibility, or *potentia propinqua*, be *in effe* at or before the particular eftate determines. (2 Rep. 51.) A remainder to a man's eldeft fon, who has none, is good; becaufe by common poffibility he may have one: but if it be limited in particular to his fon John or Richard, it is bad, if he have no fon of that name; for it is too remote a poffibility, that he fhould not only have a fon, but the fon of a particular name. (5 Rep. 51.) A limitation of a remainder to a baftard before he is born, is not good (Cro. Eliz. 505.); for though the law allows the poffibility of having baftards, it prefumes it to be a very remote and improbable contingency. In the fecond cafe, where land is given to A for life, and in cafe B furvives him, then with remainder to B in fee: here B is a certain perfon, but the remainder to him is a contingent remainder, depending upon the uncertainty of his furviving A. During the joint lives of B and A, it is contingent; and if B dies firft, it can never veft in his heirs, but is for ever gone; but if A dies firft, the remainder to B becomes vefted. Contingent remainders of either kind, if they amount to a freehold, cannot be limited on an eftate for years, or any other particular eftate, lefs than a freehold. Thus, if land be granted to A for ten years, with remainder in fee to the right heirs of B, this remainder is void (1 Rep. 130.); but if granted to A for life, with a like remainder, it is good. Contingent remainders may be defeated, by deftroying or determining the particular eftate upon which they depend, before the contingency happens, by which they become vefted. 1 Rep. 66. 155.

In devifes by laft will and teftament, remainders may be created in fome meafure contrary to the rules here laid down: though our lawyers will not allow fuch difpofitions to be ftrictly remainders; but call them by another name, that of executory devifes, or devifes hereafter to be executed. Blackft. Com. book ii. chap. 11. § 3.

Spelman makes the difference between a remainder and reverfion to confift in this; that by a reverfion, after the appointed term, the eftate returns to the donor, or his heirs, as the proper fountain; whereas by remainder it goes to fome third perfon or ftranger.

Or, a remainder is an expectancy, created by act of the parties; whereas a reverfion is created by act of law.

The limitations of perfonal goods and chattels, in remainder after a bequeft for life, are permitted in laft wills and teftaments: fo that if a man, either by deed or will, limits his books or furniture to A for life, with remainder over to B, this remainder is good. But where an eftate-tail in things perfonal is given to the firft or any fubfequent poffeffor, it vefts in him the total property, and no remainder over fhall be permitted on fuch a limitation. 1 P. Wms. 290.

Glanville obferves, that bifhops and abbots, in regard their baronies are the king's alms, cannot give any part of them by way of remainder.

Remainder, *Writ of formedon in the.* See Formedon.

Remainder, in *Mathematics*, is the difference; or that which is left after the taking a leffer number, or quantity, from a greater.

REMAL, in *Geography*, a town of Hindooftan; 18 miles N.W. of Agimere.

REMALAND, a town of France, in the department of the Orne, and chief place of a canton, in the diftrict of Mortagne. The place contains 1702, and the canton 11,68[illegible] inhabitants, on a territory of 202½ kiliometres, in 12 communes.

REMANCIPATE, *To*, in *Commerce*, is to fell or return a commodity to him who firft fold it.

REMANCIPATION, Remancipatio, among the Romans, a form of divorce obferved in marriages that had been contracted by *coemption*. This was done by delivering the wife into the hufband's hands; fo the marriage was diffolved

folved by the hufband's re-delivering the wife into any perfon's hands agreed upon between them.

REMAND, Fr., *To*, in *Military Language*, to fend back; as when a foldier, who has been brought out of prifon, or the guard-houfe, for the purpofe of being examined or tried, is fent back, without any thing final occurring relative to his cafe.

REMANSO, in *Geography*, a town of South America, in the province of Cordova; 170 miles N. of Cordova.

RE-MARRYING, the repeating of a marriage; or the going through the folemnities of a fecond marriage.

Clandeftine and uncanonical marriages are deemed null; and the parties are to be re-married in form; at leaft, it had always better be fo to avoid difputes.

It was anciently exprefsly forbid to re-marry in the firft year of viduity. M. Bayle obferves, that a perfon who does not re-marry, is anfwerable to the public for all the time loft in his viduity, or widowhood.

REMBANG, in *Geography*, a town on the N. coaft of the ifland of Java, where the Dutch had a refident merchant. It yields falt and timber, and was the place where the fmall veffels of the company were built; 45 miles N.E. of Samarang.

REMBERTUS, in *Biography*, the difciple, friend, and fellow labourer of Anfgarius, ftyled the apoftle of the north, was a native of Thurholt, in Flanders, in the monaftery of which, as well as in that of Corbey in Weftphalia, he officiated as fchool-mafter. He was one of the firft promoters of Chriftianity in Denmark, and in or about the year 860 he became bifhop of Ribe. After the death of Anfgarius, in 865, he was appointed to the archbifhopric of Hamburgh, which office he held till his death, in 888. He wrote, in conjunction with a friend, the life of Anfgarius, which is inferted in the firft volume of Langebeck's "Scriptores Rerum Danicarum." In this work Rembertus relates various facts, not elfewhere to be found, with regard to the ftate of Denmark at that period, but intermixed with fables. He collected extracts from Gregorius Magnus, whofe works no longer exift, and he wrote many letters, one of which only is to be found in the fecond volume of Langebeck's collection. An account of Rembert's life and miracles is given in the fame work. A Danifh writer, quoted in the General Biography, to which we are indebted for this article, in fpeaking of Rembert's labours, fays; "here we have not fo much the commencement of Danifh literature, as the feeds of it. They were fown by the exertions of Ebbo, Willehad, Anfgarius, and Rembert, but remained a long time, as it were, trodden down by the fevere perfecutions to which the Chriftians were expofed from Gormo the old, and other kings; and retarded in their growth by the rudenefs and barbarifm which formed the principal features in the character of a people, who were fonder of roving about on the feas to rob and murder, and of feafting and drinking, than of reading and writing books. At length, however, the feeds which he had fcattered took root, fprung up in the 11th century, and in the 12th and 13th produced abundance of fruit." Gen. Biog.

REMBERVILLERS, in *Geography*. See RAMBERVILLERS.

REMBRANDT, VAN RYN, in *Biography*, was born at a village near Leyden, in 1605. The real name of his family was Gerretfz; but he acquired that of Van Ryn, from having refided in early life at a village upon the banks of the Rhine.

The little which this extraordinary artift owed to tuition was derived firft from Zwanenburg, then from Peter Laftman, and afterwards from Jacob Pinas, from whofe manner fome are induced to think that Rembrandt drew his own inclination for powerful oppofitions of light and fhade; but whatever hints he may have obtained from others at the outfet of his practice, they were foon loft in the effulgence of his brilliant career, and abforbed in the luftre of his own over-powering abilities.

He was firft brought into notice by having taken a picture to the Hague, and offered it for fale to an able connoiffeur; who, confcious of his merit, treated him with kindnefs, and gave him a hundred florins for it. By this incident both himfelf and the public were made acquainted with his worth; and hence arofe the reputation and fuccefs he afterwards enjoyed. Inceffant occupation foon crowded upon him, and many pupils applied for admiffion into his fchool, with each of whom he received 100 florins a-year; and whofe copies of his pictures he not unfrequently fold as originals, after beftowing a fhort time upon them himfelf. By thefe means, aided by inceffant induftry, and the fale of etchings, which he produced with great facility and fkill, he accumulated confiderable wealth: his income, according to Sandrart, being, for a length of time, at leaft 2500 florins yearly.

His place of refidence, during this fuccefsful difplay of his talents, was Amfterdam, where his peculiarities procured him the character of a humorift, whilft his abilities aftonifhed and delighted his contemporaries, and he produced thofe works which ftill gratify fucceeding ages.

The peculiarities of his mind are as much obfervable in the manner of producing his effects, as in the choice of the materials. The execution of his earlier works was in a ftyle highly laboured, with great neatnefs, and patient completion of the figures; fuch is that of the picture of the woman taken in adultery at Mr. Angerftein's. As he advanced in art, he took liberties with the pencil, wrought with all the broad fulnefs of the brufh, and left the touch undifturbed: he even employed the ftick, the pallet-knife, or his fingers, accordingly as they were moft capable of producing the effect he defired, when feen at a proper diftance, difregarding the appearance of the work upon a clofer infpection.

In his pictures is exhibited a total inattention to the tafte of the antique; he is even faid to have made it a fubject of ridicule, and to have jocofely denominated a collection of old armour and rich dreffes, which he had collected and employed to ftudy and paint from, "his antiques." Thefe he evidently ufed as his models, though frequently in moft heterogeneous combination; but by an innate power of feizing the moft ftriking effects produced by light and fhade, fuperadded to the moft perfect maftery over the materials of the pallet, he always excited an intereft, either by originality or beauty.

It is not, however, the approval of his power in the technical part of the art, which can or ought to fatisfy the obferver of the works of Rembrandt. Entering with the warmth of a poet into the nature of his fubjects, he produced pictures which terrify with their fublimity, delight with their fuavity, or gratify us with the moft perfect tranfcripts of Nature, in her moft varied afpects. Being himfelf poffeffed of the full force of his fubject, he impreffes it ftrongly, and notwithftanding the frequent vulgarity, and even deformity of the agents he exhibits, he extorts from us praife before we have time to confider the means by which we are ftimulated to beftow it. To him every time and feafon was alike eafy of reprefentation; and all degrees of illumination, in form or quantity, he managed with the greateft perfection; no matter whether the fcene arofe from the breadth of the noon-day blaze, the dimnefs of twilight,

the

the darknefs of night, or the glimmerings of the lonely taper; whether the light were fpread over an extended fpace and a multitude of figures, or confined to the interior of a room, and ferving only to illumine the books or the figure of a fequeftered philofopher.

He was certainly a genius of the firft clafs, although the objects upon which he exercifed his powers bore little or no proportional value when compared with thofe felected by the beft Greek and Italian mafters. His invention was abundantly fertile, but employed generally among low characters and materials, although the fubject he treated might be, as it frequently was, of a facred or fublime quality. In defigning the nude, he never appears to have had a thought of an elevated nature concerning form. Such as the model prefented, he imitated with exactnefs, when he wifhed to be moft perfect; but he fometimes feems to have fported with the idea of felection, by making figures demanding grace and beauty, fuch as Venus, Cupid, &c. ftill more vulgar, and in actions more difgufting, than thofe he drew of common life. The redemption of this vulgarity and meannefs refts with the extreme force, depth, richnefs, brilliancy, and truth of his colouring, and the perfection with which he treated his chiaro-fcuro; which conjointly fafcinate the eye, and hold it in admiration, in fpite of the deformities prefented in defign.

The power of Rembrandt in the art he practifed was perfectly original, and its exercife quite unlike that of any other painter; being drawn from nature with the moft faithful and difcriminating eye, but with the moft peculiar felection. Always powerfully and beautifully executed, but not unfrequently too artificial; and only agreeable becaufe it is perfectly effective. All imitations of his ftyle which are not well wrought, reduce it to manner, and only exhibit the artifice by which it is conducted.

To guefs from the number and finifh of his works, he muft have painted with amazing facility. His fyftem appears to have been that of ufing the ground as a half teint, and repeating the lights and darks till he had obtained the effect he fought for. His pencil, particularly in his earlier and more finifhed works, is remarkably delicate, yet full; and has never been exactly imitated; though fome of his fcholars, as Bohl and Eckhout, approached very near it: none of them, however, appear to have imbibed any large portion of his clear perception of natural effects, which fo powerfully appeals to our fympathy in his fcenes of twilight, of tempeft, and the fpirit-ftirring gloom of night.

His pictures are juftly and highly valued, and are rarely to be purchafed; and then only at very high prices. We are poffeffed of many fine fpecimens of his talents, both in hiftory and portraiture; and the gallery of the Louvre is rich in his fmaller productions. At Florence alfo, and at Genoa, his name is efteemed, and his works preferved with due refpect.

He lived to the age of fixty-eight, and died in 1674.

REMDA, in *Geography*, a town of Saxony, in the principality of Eifenach; 11 miles S.S.W. of Jena. N. lat. 50°45′. E. long. 11° 19′.

REMEDIAL *Part of a Law*. See Law.

Remedial *Statutes*, are thofe which are made to fupply fuch defects, and abridge fuch fuperfluities, in the common law, as arife either from the general imperfection of all human laws, from change of time and circumftances, from the miftakes and unadvifed determinations of unlearned judges, or from any other caufes whatfoever. And this being done, either by enlarging the common law where it was too narrow and circumfcribed, or by reftraining it where it was too lax and luxuriant, hath occafioned another fubordinate divifion of remedial acts of parliament into enlarging and reftraining ftatutes. *E. gr.* In the cafe of treafon, clipping the current coin of the kingdom was an offence not fufficiently guarded againft by the common law; therefore it was thought expedient by ftatute 5 Eliz. cap. 11. to make it high treafon, which it was not at the common law; fo that this was an enlarging ftatute. At common law alfo fpiritual corporations might leafe out their eftates for any term of years, till prevented by the ftatute 13 Eliz. cap. 10. This was, therefore, a reftraining ftatute. Blackft. Com. book i.

REMEDIOS, in *Geography*, a town of South America, in the province of Popayan; 71 miles S. of Santa Fé de Antioquia.

Remedios, or *Noftra Segnora de los Remedios de Pueblo Nuevo*, a town of Mexico, in the province of Veragua; 90 miles W.N.W. of St. Yago. N. lat. 8° 44′. W. long. 82° 16′.

Remedios, or *Payafal*, a town of Mexico, in the province of Yucatan, in lake Pue. N. lat. 17° 3′. W. long. 91° 46′.

Remedios, a town of New Navarre; 120 miles S. of Cafa Grande.

REMEDY, in *Law*, is the action or means given by law for the recovery of a right.

Remedy, *Remedium*, in *Medicine*, any phyfical agent by which a difeafe may be alleviated or cured.

Remedies are either *general* or *topical*; the former comprehending fuch as influence the actions of the whole frame, as blood-letting from any large vein, the cold-bath, and almoft all thofe medicaments or drugs which are taken into the ftomach; the latter including thofe which are applied to, or in the vicinity of, any particular part which is difeafed: thus, among *topical* remedies, are blood-letting by leeches or cupping, blifters, iffues, cataplafms, ointments, plafters, &c.

The operation of remedies is rather a queftion of experience than of logical inveftigation. Some remedies, the number of which appears to be very limited, poffefs a *fpecific* power of curing certain difeafes. There are, perhaps, not more than two medicines, however, that are fairly entitled to the appellation of *fpecifics*: thefe are mercury, which cures the venereal difeafe, and fulphur, which cures the itch. The bark of cinchona has, indeed, been deemed a fpecific for intermittent fevers; but it is not entitled to fuch a character: and the eau medicinale, which has recently been brought forward as a fpecific for the gout, appears to have loft much of its reputation. The pretended fpecifics daily advertifed for many difeafes by quacks, are mere impofitions, being commonly difguifed forms of the moft active and dangerous medicines which are employed cautioufly by the faculty; fuch as arfenic, corrofive fublimate, and other preparations of mercury; laudanum, hemlock, and other narcotics. Of the former fpecies are Ward's ague-drop, and his white drop; of the latter, are Dalby's carminative, Godbold's balfam, and many others. The danger refulting from the ufe of thefe noftrums, arifes from the indifcriminate adminiftration of them in many difeafes which have a fimilar name, but which vary much in different conftitutions, and at different periods of life. Much injury is done by the conftant fale of thefe pretended fpecifics, by the impreffion which it contributes to maintain, that each difeafe has its fpecific remedy; whereas no opinion can be farther from the truth. When it is confidered that almoft every difeafe, though fimilar in name, arifes from feveral caufes (which we have already illuftrated when fpeaking of Cough), it will be obvious that the fame remedies muft be applied, upon general principles, to difeafes of different name, and different remedies to thofe which have the fame same appellation; and that, therefore, the cure of diseases is not to be effected by applying a certain remedy to a certain disease nominally the same, but only by first ascertaining the laws of the living body, and of its various organs, both in a state of health and of disease: in other words, the proper application of remedies can only be learned by much observation of diseases, after a previous study of the anatomy and physiology of the animal frame.

Remedies *Appended*. See Appensa.

Remedy *for the Master of the Mint*, in *Coinage*, denotes a certain allowance for deviation from the standard weight and fineness of coins. In some places the remedy is allowed in the weight, in others in the fineness; but mostly in both weight and fineness. It is considered generally as an allowance for the fallibility of workmanship; but in some foreign mints it is made a source of emolument: and when governments issue coins at a rate above their intrinsic value, the profit thus made is called "seignorage." Out of every fifteen pounds of gold coined at the mint in London (according to the account published by the learned Mr. Folkes, in his curious tables of English silver coins), some pieces are taken at random, and deposited in a strong box, called the pix: at certain intervals, sometimes of one year and sometimes of several years, the pix is opened at Westminster, in the presence of the lord chancellor, the lords commissioners of the treasury, and others; portions taken from the pieces of each coinage are melted together, and an assay made of the collective mass by a jury of the goldsmiths' company. At this trial the mint-master is held excusable, though the monies be either too base, or too light; provided the imperfection and deficiency together are less than the sixth part of a carat, which amounts to forty grains of fine gold on the pound of standard, or the one hundred and thirty-second part of the value. It is said that this remedy is contained within as narrow limits, as any workers can reasonably be supposed to make themselves answerable for. The remedy for silver coins is two pennyweights in the pound. If the deficiency or excess of the coin should be more than this, either in the weight, or in the fineness, or in both together, the money must be recoined at the expence of the master of the mint; and no allowance is made for remedy unless the error is supposed to have casually happened.

REMEE, in *Geography*, a town of Bengal; 16 miles S. of Koonda.

REMEMBRANCE, is when the idea of something formerly known recurs again to the mind, without the operation of a like object on the external sensory. See Memory, Reminiscence, and Recollection.

REMEMBRANCERS *of the Exchequer*, are two officers, or clerks, therein, formerly called *clerks of the remembrance*.

They are now distinguished by the appellations of the *king's remembrancer*, and the *lord treasurer's remembrancer*. There is also another officer, called the *remembrancer of first-fruits*. Their business is to put the lord treasurer and justices of the court in remembrance of such things as are to be called upon, and dealt in for the king's benefit.

Rememberancer, *The King's*, enters into his office all recognizances taken there before the barons, for any of the king's debts; for appearance; or for observing orders; and makes out process against the collectors of customs, subsidies, excise, and other public payments, for their accounts. All informations upon penal statutes are entered in this office; and there all matters upon English bills in the exchequer-chamber remain. He makes the bills of composition upon penal laws; takes the statement of debts; has delivered into his office all manner of indentures, fines, and other evidences whatsoever that concern the assuring of any lands to the crown: he every year, *in crastino Animarum*, reads, in open court, the statute for election of sheriffs, and gives them their oath, and reads the oath of all the officers of the exchequer, where they are admitted.

Remembrancer, *The Lord Treasurer's*, is charged to make process against all sheriffs, escheators, receivers, and bailiffs, for their account; process of fieri facias, extent for any debts due to the king, either in the pipe, or with the auditors; and process for all such revenues as are due to the king, by reason of his tenures. He also makes record, by which it appears, whether sheriffs, or other accountants, pay their proffers due at Easter and Michaelmas. He makes another record, whether sheriffs, or other accountants, keep their days of prefixion: all estreats or fines, issues, and amerciaments, set in any of the courts of Westminster, or at the assizes or sessions, are certified into his office, and are by him delivered to the clerk of the estreats to write process upon them, &c.

Remembrancer *of the First Fruits*, he who takes all compositions and bonds for first fruits and tenths; and makes process against such as do not pay the same.

Remembrancer is also the title of an officer in the city of London, who is to attend the lord mayor on certain days, and whose business is to remind his lordship of the select days, when he is to go abroad with the aldermen, &c. He is to attend daily at the parliament-house during the sessions, and to report to the lord mayor their transactions.

REMI, St., in *Biography*, archbishop of Rheims, who converted Clovis to Christianity, and baptized that monarch. He died about the year 535. There are some letters which pass under his name, but they are of a very doubtful authority. There was another saint of this name, or, as he is sometimes styled, Remigius, who was archbishop of Lyons, and presided in the council of Valentia in 855. He was a steady supporter of the doctrine of St. Augustine, on grace and predestination, in several works that are now extant. He died in 875.

Remi, Joseph Honore, an advocate in the parliament of Paris, was born in 1738. At the age of eight he lost his sight, and it was believed irrecoverably, by the small-pox; but when he had attained the age of fourteen he was in the enjoyment of his eyes. He was author of a burlesque poem, entitled "Days," in opposition to Young's Night Thoughts; but his principal work is an eloge on the chancellor de L'Hôpital, which was crowned by the French academy in 1777, and censured by the Sorbonne. He also wrote the eloges of Moliere, Colbert, and Fenelon, and furnished the articles relating to jurisprudence for the French Encyclopædia. He died in the year 1782.

Remi of Auxerre. See Remigius.

Remi, *Order of St.*, or of the *Holy Vial*, an order of knighthood in France, which, according to the most approved historians of that kingdom, was instituted by Clovis, king of France, in the year 499. The reigning king of France is always sovereign of this order, and the knights companions are never more than four; nor is it ever conferred on any persons but the barons, Terrier, Belestre, Venestre, and Louverse, who stile themselves baron knights of the Holy Vial, and are the bearers of the canopy under which the vial is carried from the abbey of St. Remi to the cathedral of Rheims, for the inauguration of the kings of France at their coronations. The badge of this order, which is worn pendant to a black ribbon, is "a cross of gold, enamelled white, cantoned with four fleur-de-lis; on the cross, crofs, a dove defcending, dipping its beak into a vial held in a hand, all proper."

REMICH, in *Geography*, a town of France, in the department of the Forefts, and chief place of a canton, in the diftrict of Luxembourg, feated on the Mofelle; 12 miles E. of Luxembourg. The place contains 1480, and the canton 10,885 inhabitants, on a territory of 230 kiliometres, in 15 communes.

REMIGES, in *Ornithology*, denote the primary and fecondary wing-feathers.

REMIGIO, Fiorentino, in *Biography*, a man of letters in Italy, was a native of Florence. He entered at an early period into the Dominican order, and was called to Rome by pope Pius V. to fuperintend an edition of the works of St. Thomas. He was himfelf a confiderable author, and publifhed "A Commentary on the whole Scriptures;" tranflations of "Ammianus Marcellinus;" "Cornelius Nepos;" and "Fazello's Hiftory of Sicily;" "Reflections on Guicciardini's Hiftory;" "Italian Poems;" and "A Tranflation in Verfe of Ovid's Heroic Epiftles," of which an elegant edition was printed at Paris in 1762. He died at Florence in 1580, about the age of 62. Moreri.

REMIGIUS. See Remi.

Remigius of Auxerre, a learned French Benedictine monk in the ninth century, derived his furname from the abbey of St. Germain, at Auxerre, where he embraced the religious profeffion. He diftinguifhed himfelf by his proficiency in profane and facred literature, at a dark and barbarous period, and was placed at the head of the fchools belonging to his monaftery. About the year 882, he was called to Rheims by Foulques, the fucceffor of Hincmar in that fee, who gave him the direction of the literary feminary which he had founded in his metropolitan city. Here he taught with great reputation for feveral years, after which he went to Paris, where he opened the firft public fchool in that city, after the decline of learning which followed the ravages of the Normans. In the life of pope Formofus, by Platina, the name of Remigius of Auxerre is the only one that occurs of a perfon eminent for learning under that pontificate. He was author of "Commentarius in omnes Davidis Pfalmos," which was publifhed at Cologne in 1536. It confifts very much of the collected opinions and explications of St. Ambrofe, St. Auguftine, and Caffiodorus, reduced into one mafs.—Another work of this author was entitled "Enarratio in pofteriores XI. minores Prophetas," publifhed at Antwerp in the year 1545, with the "Commentaries" of Oecumenius upon the Acts of the Apoftles, and their Epiftles, and thofe of Arethas upon the book of Revelation; and "Expofitio Miffæ," deduced from the fentiments and authority of the fathers. Some critics have given, among the productions of Remigius, the "Commentary upon the Epiftles of St. Paul," which by others has been afcribed to St. Remi, or Remigius, but which in truth are fuppofed to belong to Haymo, a German bifhop, who flourifhed in the ninth century, and who was author of a long lift of theological works. Such at leaft is the opinion of Du Pin, in oppofition, indeed, to the authority of Mofheim. Moreri.

Remigius left behind him "A Commentary on the Mufical Treatife of Martianus Capella," which is ftill fubfifting among the MSS. in the king of France's library, N° 5304. He acquired his fcience from Heric. Heric was the difciple of Rabanus, and Hayman of Halberftadt, who had converfed with the Roman fingers fent into France by pope Adrian.

REMILLY, in *Geography*, a town of France, in the department of the Ardennes; 7 miles W. of Charleville.

REMINISCENCE, Reminiscentia, is that power of the human mind, by which it recollects itfelf, or calls again to its remembrance fuch ideas or notions as it had really forgot: in which it differs from *memory*, which is a treafuring up of things in the mind, and keeping them there, without forgetting them.

Hence memory may be confidered as a continual remembrance; and reminifcence as an interrupted memory.

How near akin foever the two faculties may feem, yet they are generally found feparated; fo that they who excel in the one, are generally defective in the other.

The ancient Platonifts were of opinion, that all learning and knowledge confifted in the reminifcence or recollection of notices which had been in the foul before its union with the body.

REMINISCERE, the fecond Sunday in Lent; anciently thus called from the firft word of the introit of the mafs faid for that day, "Reminifcere miferationum tuarum."

REMIREA, in *Botany*, Aubl. Guian. 44. t. 16. Brown Prodr. Nov. Holl. v. 1. 236. (See Miegia.) We are unacquainted with Mr. Brown's reafons for preferring the above name, whofe origin does not appear, and which the claffical Schreber rejected as barbarous.

REMIREMONT, in *Geography*, a town of France, and principal place of a diftrict, in the department of the Vofges; 10 miles S.S.E. of Epinal. The town contains 3250, and the canton 14,916 inhabitants, on a territory of 235 kiliometres, in 15 communes. N. lat. 48° 1'. E. long. 6° 40'.

REMISIT. — *Recto quando dominus Remifit.* See Recto.

REMISSAM, in *Geography*. See Remsa.

REMISSION, in *Law*, &c. denotes the pardon of a crime, or the giving up the punifhment due to it.

Remission, in *Medicine*, is when a diftemper abates, but does not go quite off, before it returns again: as is common in fevers which do not quite intermit. See Remittent.

Remission, *Remiffio*, in *Phyfics*, the abatement of the power or efficacy of any quality. In oppofition to the increafe of the fame, which is called its *intenfion*.

In all qualities capable of intenfion and remiffion, the intenfion decreafes as the fquares of the diftance from the centre of the radiating quality increafe.

Remission, *Remiffio*, ἄνεσις, in the *Ancient Mufic*, was ufed to fignify the paffage of the voice from acute to grave, being oppofite to intenfion.

REMIT, in *Commerce*. To remit a fum of money, bill, or the like, is to fend a fum of money, &c.

To remit is alfo ufed among bankers for what is accuftomed to be given a banker, or, as it were, difcounted with him, for his giving a bill of exchange.

To remit is alfo to give up part of one's due to a debtor; as, I would remit you a fourth of what you owe on condition of paying me the reft in hand.

REMITTANCE, in *Commerce*, the traffic or return of money from one place to another, by bills of exchange, orders, or the like.

A remittance is properly a bill of exchange, or the like, fent to a correfpondent, and the content of it to be received by him, or fome other perfon, on whom it is drawn. By means of thefe remittances, large fums of money are returned from one city to another, without danger, without carriage, &c.

In London it is eaſy to get remittances upon any city in the world; in the country it is more difficult.

Remittances, *Book of.* See Book.

Remittance is alſo uſed in ſpeaking of the payment of a bill of exchange.

Remittance alſo denotes the due or fee allowed the banker or merchant, both on account of his trouble, and the different value of the ſpecies in the place where you pay the money, and where he remits it.

This remittance is more uſually called *change* and *rechange*.

REMITTENT, in *Medicine*, implying alſo the word *fever*, is a fever which is characteriſed by a regular decreaſe and exacerbation of its ſymptoms every day, and differs from an *intermittent*, inaſmuch as the ſymptoms never diſappear altogether, and the exacerbation is neither begun by the complete rigors, nor terminated by the profuſe ſweat, which occur in the latter. The remittent fever, however, originates, in common with the intermittent, from the influence of marſh effluvia, but under particular circumſtances, which will be ſtated immediately.

It is ſcarcely neceſſary to deſcribe minutely the ſymptoms of the remittent fever after the ample detail which we have given of thoſe of fever in general (ſee Fever); and it varies extremely in its character, according to the ſeaſon, climate, and other circumſtances under which it appears. In its milder forms, the remittent begins with chillineſs, laſſitude, pains in the bones, head-ache, and a diſordered condition of the ſtomach, loſs of appetite, ſickneſs, and even vomiting. At night the febrile ſymptoms run high; the heat and thirſt are great, the tongue and mouth are parched, the pain of the head is violent, the patient is totally unable to ſleep, and is continually toſſing and tumbling about, and often becomes delirious. But generally in the morning, an imperfect ſweat brings on a remiſſion of all the ſymptoms. In the evening, the paroxyſm returns, but is not preceded by any cold ſit or ſhivering; yet it is commonly more ſevere than the former. Next morning it remits as before; and theſe periodical changes recur daily, becoming, however, leſs marked, if the diſeaſe be neglected, until the fever inſenſibly aſſumes a continued form. The pulſe is full and quick during the exacerbations, and continues during the remiſſions to indicate fever; but rigors ſeldom precede the fits after the firſt attack. Many patients diſcharge a bilious matter from their ſtomachs by vomiting, and all are diſordered in that organ. In the more violent forms, which take place in hotter ſeaſons and climates, the diſeaſe often ſeizes the patient at once with a burning and violent head-ache, with little or no ſenſible chillineſs preceding it. The thirſt and heat are intenſe, and acute pains in the back and all the limbs, with extreme laſſitude and inquietude, haraſs the patient, and nauſea, vomiting, and pain of the ſtomach enſue. In ſome inſtances, indeed, the head becomes ſo ſuddenly and violently affected, that a violent delirium, aſſuming the appearance of inſanity, ſeizes the patient without any previous indication, until the remiſſion evinces the nature of the diſeaſe. Many of the ſick become yellow, as if affected with jaundice. Indeed, the remittent fever aſſumes every degree of violence, from the autumnal bilious fever of temperate climates, to the moſt ſevere *yellow fever* of tropical countries.

The circumſtances under which theſe varieties of form occur, have been amply aſcertained by experience. The combination of marſh effluvia and great heat are neceſſary to the production of theſe fevers; and they are violent, nearly in proportion to the degree of the latter. In cold climates, and in cool ſeaſons, as the ſpring, the miaſmata excite but the common intermittent ague. But in the autumnal ſeaſon, eſpecially when the heat is conſiderable, and the quantity of miaſma great, as in the Low Countries, in particular years, the production of theſe fevers is very extenſive; they become actually endemic, and affect eſpecially thoſe perſons who are not accuſtomed to the climate. The experience of all our military expeditions to Holland and Flanders, in the autumnal ſeaſon, affords fatal proof of this truth. (See the writings of ſir John Pringle, Dr. Home, &c. on the Diſeaſes of the Army in the Campaigns of 1742—1748, incluſive. And the ſevere epidemic of Walcheren, at a more recent period, cannot be forgotten.) In theſe climates, the *remittent* uſually commences at the cloſe of ſummer, in a milder form, and gradually aſſumes a more violent and formidable character, as the heats of autumn advance. But if we extend our inquiries to the hotter regions of the globe, we find the diſeaſe under its moſt ſevere and fatal forms. In the ſouth of Europe, eſpecially in Spain, and thoſe parts of the Mediterranean coaſts where miaſmata are found, the autumnal remittent becomes a formidable malady in particular ſeaſons; but we muſt proceed to the Weſt Indies and America to diſcover the diſeaſe in its moſt terrific form; for although there may be a contagious fever, which puts on the *yellow* or bilious character, Dr. Bancroft appears to have demonſtrated, ſatisfactorily, that the *yellow fever*, commonly ſo called, is but the ſevereſt form of the endemic remittent of the hot ſeaſons of hot climates. (See his able "Eſſay on the Diſeaſe called Yellow Fever, &c." 1811). He affirms, indeed, that all fevers, occurring in thoſe countries in which the atmoſpheric heat riſes, during certain ſeaſons, to the 85th degree of Fahrenheit's thermometer, have a tendency to aſſume that violent and dangerous appearance, which is uſually conſidered as characteriſtic of the yellow fever.

The teſtimony of all experienced medical obſervers concurs in proving the origin of remittent fevers from the influence of miaſmata. Thus, among the hiſtorians of diſeaſe, as it occurs among ſeamen in warm climates, Drs. Lind, Blane, Hunter, and others, have demonſtrated the excluſive attacks of theſe fevers to be among thoſe men who have gone on ſhore, in ſwampy grounds, for water, &c.; and eſpecially among thoſe who ſpend the night on ſhore. Many inſtances are recorded, in which all the men ſo employed have been ſeized with fevers, while the reſt of the ſhip's company have remained in health. (See Dr. Lind, on the Diſeaſes incidental to Europeans in Hot Climates, p. 27. 221, &c. 5th edit. Dr. Blane, on the Diſeaſes of Seamen, p. 92, and 392.) Again, ſir John Pringle, in his valuable work on the diſeaſes of the army, has not only ſtated many facts which occurred under his own obſervation, but has adduced many proofs from the writings of ancient phyſicians and hiſtorians, in corroboration of the evidence that theſe fevers have, every where, and at all times, originated in hot ſeaſons, in circumſtances where miaſmata exiſted. (Part 3. chap. iv. ſect. 3.) In times, indeed, not very remote, when the want of proper means of carrying off the filth and refuſe of large towns by proper drains, and ſcavengers were not employed, and when the materials for the production of miaſmata were accumulated even in the ſtreets, the remittent and intermittent fevers were epidemic, in favourable ſeaſons, for the generation of the miaſmata, and the ſource of conſiderable fatality. Thus, even in London, Dr. Short remarks that, early in the ſeventeenth century, "one of forty of the whole that died of fevers, died of agues." (See his New Obſervations, &c. on Bills of Mortality, p. 203.) And Burnet, in his Hiſtory of the Reformation, ſays, that in the laſt year of queen Mary's reign, they "raged like a plague." At a later period, we have

have the teſtimony of Sydenham and Morton, in proof of the great prevalence of remittents in London; and Morton affirms that they were extremely deſtructive for ſeveral years before the great plague, *viz.* from 1658 to 1664. He ſtates that Oliver Cromwell died of an attack of remittent fever in the former of theſe years, and that he loſt his own father, who was himſelf an experienced phyſician, from the ſame diſeaſe, which had gone through his whole family. (Morton, Pyretologia, append. ad Exerc. ii.) "The reſult of the whole, therefore, is," to uſe the words of ſir John Pringle, "wherever the greateſt cauſes of moiſture and putrefaction in the air exiſt, there alſo will be ſeen the greateſt number and the worſt kinds of the remitting and intermitting fevers." This truth is farther confirmed by the negative evidence, that theſe fevers have ceaſed to exiſt where marſhes have been drained, where towns have become cleanly, when armies have moved to dry ſituations, and when the heats of particular ſeaſons have ceaſed, or failed to occur.

What the nature of theſe miaſmata is, the inveſtigations of philoſophers have not yet taught us. Dr. Bancroft has entered at great length, and with great ability, into this queſtion, reaſoning from a large collection of important evidence. He details a number of intereſting facts, which ſeem to lead ſatisfactorily to the concluſion, that the mere exhalations from *putrefying animal matter*, however offenſive to the ſenſes, are never productive of fevers. The ſame inference has been deduced, not leſs ſatisfactorily, by Dr. Chiſholm, in a very elaborate and able diſſertation upon this topic, publiſhed in the Edinburgh Medical and Surgical Journal for October, 1810, vol. vi. p. 389. However contrary to the general opinion, this doctrine, that mere putrefaction is not the ſource of contagion and fever, appears, indeed, by theſe writers to be eſtabliſhed. The experiment, in fact, has been tried on a large ſcale in France, in the caſe of the prodigious exhumations made in the church-yard of St. Eloi, at Dunkirk, in 1783, and in that of the ſaints Innocents at Paris, in 1786. In the latter caſe, nearly 20,000 bodies were taken up, in every ſtage of putrefaction, and a conſiderable part of the work was carried on during the greateſt heats of ſummer, rendering the whole city offenſive; yet no fever was occaſioned by this immenſe maſs of corruption. (See M. Thouret's Memoir in the Journal de Phyſique, for 1791, p. 253; and the Annales de Chimie, vol. vi.) The good health of nightmen, of perſons living in diſſecting-rooms, of thoſe employed in the manufactory near Bath of a ſort of ſpermaceti from putrefying fleſh of all deſcriptions, and many other ſtriking facts, detailed by the two authors juſt quoted, conſtitute a ſtrong evidence in proof of the abſence of inſalubrity from mere putrefaction.

Dr. Bancroft next proceeds to prove, by another ample collection of facts and teſtimonies, that it is not the mere *aqueous vapour* that conſtitutes the morbific quality of marſh-miaſms. The principal proofs that mere moiſture is incapable of producing theſe fevers, are, that ſailors at ſea for many months are generally very healthy; that no ſet of men are more uniformly ſo than the Newfoundland fiſhermen, who are uſually enveloped in the dampeſt fogs for ſeveral months together; that while perſons living on ſhore on unwholeſome iſlands, as at Walcheren, are ſpeedily attacked with fevers, thoſe who remain on ſhip-board, at a little diſtance from land, entirely eſcape them; and that the occurrence of theſe fevers has been frequently prevented by laying ſwampy ground under water, under which circumſtances the moiſture of the atmoſphere muſt be highly augmented.

Conſidering, then, that the mineral part of the ſoil is not vaporizable in any natural heat, and that animal ſubſtances in a ſtate of putrefaction are incapable of producing fever, as well as the mere aqueous vapour, Dr. Bancroft was diſpoſed to conclude, that the morbific exhalations in queſtion ariſe wholly from "the mutual decompoſition of vegetable matters and water;" and that thoſe ſwampy grounds are moſt likely to emit them, which contain the largeſt proportion of ſuch matters, and in which the decompoſition is moſt rapid and complete. This concluſion, he is of opinion, is confirmed by the facts that the exhalations from macerating hemp and flax are well known in Italy to produce fevers, and that thoſe ariſing from heaps of decaying indigo, in the Eaſt and Weſt Indies, have produced the ſame effects. See his Eſſay on Yellow Fever, above quoted.

Of the Treatment of Remittent Fevers.—As the violence of the ſymptoms, and conſequently the actual character of theſe diſeaſes, vary materially in different ſeaſons, climates, and circumſtances, under which they occur; ſo no uniform rule of treatment can be purſued for their cure. The ſame remedies, indeed, which at one period of the ſame fever are beneficial, are hurtful if reſorted to at another. This obſervation, however, is applicable to all febrile diſeaſes, and cannot be too often inculcated; ſince not only empiriciſm, but the routine of too many of the profeſſion, tends to the appropriation of ſome leading remedy, whenever the name of a particular fever is mentioned: with ſome it is bark, with others antimony, and with others mercury; the indiſcriminate uſe of any of which muſt be neceſſarily productive of injury.

In the more violent forms of the diſeaſe, which are common in hot climates, and in which the attack is marked by a ſudden and ſevere affection of the head, with a hard, full, and ſtrong pulſe, indicating, with other ſymptoms, an inflammatory affection of the brain, perhaps the only remedy which is capable of arreſting the diſeaſe, is ſpeedy and free *blood-letting*. In the moſt violent forms of all, this evacuation ſhould be reſorted to very early, as within the firſt twenty-four hours, or the miſchief will have advanced beyond the reach of this remedy. In milder caſes, a moderate bleeding from the temporal artery or jugular vein, or even from the arm, within the firſt day or two, will often remove the danger and ſeverity of the fever. The repetition and extent of the bleedings muſt be determined by a conſideration of the violence of the ſymptoms, the duration of the diſeaſe, and the vigour of the patient. The notion that theſe fevers of hot climates are of a *putrid* nature, becauſe they ſpeedily run on to ſymptoms of debility, or putreſcency, as they have been called, appear to be altogether erroneous; and it is now generally admitted, that the only effectual mode of preventing theſe ſymptoms, is by arreſting the violent inflammatory excitement in the beginning, of which they are the immediate effect.

The next moſt effectual remedy, if reſorted to alſo ſufficiently early, is purgation. The purgatives adminiſtered ſhould be ſuch as in bulk and quality are not calculated to offend the ſtomach, which is uſually in an irritable ſtate: calomel, with jalap, anſwers the purpoſe well; and it is in all probability by its purgative quality alone, that mercury has been found beneficial in theſe fevers. The efficacy of mercurial purgatives, indeed, ſeems to have been fully eſtabliſhed by the recent experience of our naval and military practitioners, in every quarter of the globe; while the mercurial practice, which had for its object the excitement of ſalivation, is ſhewn by Dr. Bancroft, from the teſtimony of Dr. Ruſh and others, its advocates, to have been by no means ſucceſsful.

This early excitement is alſo conſiderably alleviated by the application of *cold* in every mode. Almoſt all the modern

dern writers bear their teftimony to the important auxiliary operation of the cold and tepid affufion; although they admit that, alone, its effects are not fufficiently powerful or permanent to be depended upon. *Coolnefs* of the patient is to be promoted by every means; by the free ufe of cold aqueous drinks, by frequent wafhing, by the full admiffion of frefh air, and by the ufe of few and light coverings on the bed.

Thefe remedies fhould be actively employed, and repeated on the return or non-ceffation of the fymptoms of excitement. For as an intelligent phyfician has remarked, "the great object is the removal of the local affection of the brain, or other organ, and the production of a complete remiffion of the febrile fymptoms, in the leaft poffible time, by which the dangerous fymptoms of the latter ftages are prevented or greatly mitigated, and a perfect and rapid recovery infured." (See Dr. Burnett's Account of the Bilious Remittent Fever in the Mediterranean, p. 22. Lond. 1814.) This object is rather impeded, than affifted, by the adminiftration of emetics and fudorifics; and altogether defeated by the ufe of bark, cordials, or ftimulants of any kind, whether in the way of food or medicine. With refpect to emetics, they are objectionable in all ftages of the difeafe; for they not only fail in removing naufea, but actually increafe that diftreffing fymptom: their operation aggravates the affection of the head, of which the naufea appears to be fympathetic; and as the tendency of the difeafe is to augment irritability of the ftomach, which often becomes extreme and diftreffing in the latter ftages, fo they contribute to aggravate this and other dangerous fymptoms. Sudorifics are alfo to be condemned; for, in the firft place, they are unneceffary, becaufe a natural perfpiration will readily enfue, as foon as the excefs of heat above the ftandard of health has been removed, which can be accomplifhed with certainty by the proper application of cold water to the furface of the body; and, in the next place, the fudorifics which are ufed are apt to increafe the irritability of the ftomach; and if they fail to excite a diaphorefis, they increafe the heat and the determination to the head, and tend to lengthen the paroxyfm. With regard to the bark and cordials, they are invariably injurious in the firft ftage of the fever. When a diftinct remiffion has taken place, fome writers recommend the immediate adminiftration of cinchona; but even thefe admit, that "if it be given when there is a parched fkin, a hard pulfe, a dry tongue, great heat and pain at the ftomach, or delirium, it will generally be found to increafe and prolong thefe fymptoms." (See Bancroft, loc. cit. p. 76.) On the whole, however, the late experience in the Mediterranean led to the rejection of the ufe of bark, while any febrile fymptoms whatever remained. "Under its ufe," fays Dr. Burnett, "mortality has been great, relapfe frequent, and (as in the cafes of the Temeraire and Invincible) dyfentery attacked nearly all the patients who had fever in a fevere form; nor was there an inftance, as far as I could learn, that, when given during a fuppofed remiffion of the fymptoms, it prevented a return of the paroxyfm. Too often it has been given with wine at the commencement of this difeafe, when the tongue has foon put on a brown, dry, and furred appearance; the anxiety, delirium, and irritability of the ftomach, have been much increafed; the whole train of nervous fymptoms foon became formidable, refifting every means of alleviation, till death has put a period to the fufferings of the patient." Loc. cit. p. 34.

If any thing were wanting to corroborate the foregoing deductions from experience, in favour of the antiphlogiftic and evacuant plan of treatment, in the commencement of remittent fevers, the detail of the appearances obferved on diffection, after the death of patients in thefe fevers, would amply fupport them, by the proofs which it affords of the inflammatory condition of various organs of the body in thefe fatal cafes. In different inftances, inveftigated by Dr. Burnett and his colleagues in the Mediterranean, the veffels of *the brain* were generally diftended, and in many cafes completely gorged, with blood; the membranes of that organ were confiderably inflamed, often prefenting what that writer calls "a blood-fhot appearance," and depofitions of coagulable lymph were feen among the convolutions: there were occafionally alfo adhefions, and the ventricles were often diftended with a fluid, fometimes limpid, fometimes yellow. Appearances of *high inflammation* prefented themfelves in the cavity of the cheft, affecting the lungs, pericardium, and diaphragm; and thefe were connected with depofitions of lymph and effufions of ferum. In the abdomen, the liver was generally found enlarged, and fometimes exhibiting marks of inflammation; the ftomach diftended with air, more or lefs inflamed, and containing a dark coloured matter; and the inteftines in a fimilar condition, with frequent intus-fufception.

Thefe appearances, which are in fact the effect of the continuance of the febrile actions in the organs in queftion, fufficiently prove that the firft ftage is the time when active remedies, of an anti-inflammatory power, can be chiefly expected to produce a very decided removal of the difeafe. When the fever is a little more advanced, the principal object of the practitioner is to diminifh the violence of any local affection that may be fevere. Thus, if head-ache remains, with flufhed countenance, fuffufion of the eyes, and a firm pulfe, a fmall bleeding from the temporal artery (the pulfe being at the fame time carefully examined) may be employed with advantage: a blifter, applied to the head at this time, is alfo manifeftly beneficial; and daily evacuations of the bowels fhould be procured by gentle laxatives, fuch as caftor oil, or glyfters, the powerful cathartics being now laid afide. Irritability of the ftomach, which is often diftreffing at this period, is relieved by the effervefcing draught, and by the application of leeches, or of a large blifter to the pit of the ftomach. A degree of ftupor fometimes fupervenes, which is often removed by a blifter applied to the neck or forehead, or by the application of leeches to the temples. If there is any obvious affection of the abdominal vifcera, which fhould be carefully inquired into, blifters, and, above all, the warm bath, fhould be reforted to, as well as copious emollient glyfters.

If, however, from want of the means of relief, or from the violence of the difeafe, it has advanced to that ftage, in which the yellow fuffufion of the fkin appears, and various nervous fymptoms, fubfultus, tremors, &c. come on, with increafed uneafinefs about the ftomach, hiccup, or vomiting of a dark matter, refembling coffee-grounds, with ifchuria, and a finking or intermiffion of the pulfe, little more can be done than to look on, and endeavour to obviate fymptoms as they occur. "Singultus," to borrow again the words of Dr. Burnett, "is a dangerous, and commonly a moft haraffing fymptom at this time: it will often be relieved by camphorated julep, to which may be added opium and æther. If the pulfe fink, the ftimuli muft be increafed; and under thefe circumftances, I have found the carbonate of ammonia, with aromatic confection, of fingular benefit. But while we endeavour to reftore the circulation, *care muft be taken not to induce a ftate of fecondary excitement*; and as the pulfe rifes, the ftimuli fhould be decreafed. Conftant attention muft ftill be paid to the daily evacuation of the bowels; but at a period, when the excitability of the fyftem

tem is nearly deftroyed, powerful cathartics will be attended with the moft deleterious confequences: glyfters are particularly ferviceable at this time. As the difeafe advances, the fecretions are at times voided involuntarily: in a few I have obferved a retention of urine, and in thefe laft cafes the catheter fhould be ufed; but as a general fymptom, there is far oftener a deficiency in the fecretion of that fluid. Frequently in this ftate, the ftomach rejects every thing. We may now fafely indulge the patient *moderately* with any thing to which his fancy leads him. Bottled porter, wine, and brandy and water, have been found beneficial. But no remedy can be relied on with any degree of certainty: whatever calms the irritability of the ftomach, and moderately fupports the excitability of the fyftem, is ufeful. A few fpoonfuls of arrow-root or fago, with wine and fpice, given occafionally, will often be retained by the patient, and greatly at this period affift the cure." Burnett, loc. cit. p. 29.

During the *ftate of convalefcence* at every period, whether from a complete remiffion being procured early, or from a gradual ceffation of the difeafe, extreme caution is neceffary in regard to preventing repletion: in the former cafe, it is apt to induce a relapfe; and in the latter, it will retard the cure. During the whole progrefs of recovery, attention fhould be paid to the regularity of the bowels. Some light tonic, as an infufion of quaffia, gentian, or cinchona, with an aromatic or fulphuric acid, may be adminiftered. When the yellow fuffufion of the fkin has been great, a protracted convalefcence is commonly the confequence; and is often attended with irregular affections of the bowels, and fymptoms of indigeftion. In thefe cafes, fmall dofes of the mercurial pill, with an occafional gentle purgative of caftor oil or rhubarb, are very beneficial. It is almoft exclufively, indeed, in thefe protracted cafes, where a morbid affection of the liver, brain, or fome other vifcera, has been the refult of the uninterrupted violence of the firft ftage of the fever, and efpecially when there is reafon to fuppofe that affufion had taken place within the cranium, that mercury, in fmall dofes, is of any actual utility. Small dofes of calomel, or of the pilula hydrargyri, fhould be adminiftered until fome fenfible, but flight, effect be produced on the falivary fyftem; after which the difeafe often ceafes of itfelf, or is readily removed by the ufe of the Peruvian bark. See Burnett on the Bilious Remittent in the Mediterranean; Bancroft on the Yellow Fever; and Irvine on the Difeafes of Sicily. See alfo Fever, *Yellow*, and Miasma.

Remittent *Fever of Children*, the *febris infantum remittens* of Dr. Butter, which is a very common affection of children, when the abdominal organs are deranged, has already been defcribed at length, under the head of Infants, § 5. *Febrile Difeafes of*; which fee.

REMITTER, in *Law*. Where a man has two titles to land, and is feifed by the latter; and, that proving defective, he is remitted or reftored to the former more ancient title; this is called a *remitter*, from the Latin, *remittere, to fend back*.

If land defcend to him that had right to it before, he fhall be remitted to his better title, if he pleafe. 1 Inft. 347. *b.* Litt. § 659.

Remitter is claffed (with *retainer*) by judge Blackftone, among thofe remedies for private wrongs, which are effected by the mere operation of law, and is thus defcribed: remitter is where he, who hath the true property or *jus proprietatis* in lands, but is out of poffeffion thereof, and hath no right to enter, without recovering poffeffion in an action, hath afterwards the freehold caft upon him by fome fubfequent, and of courfe defective title: in this cafe, he is remitted, or fent back, by operation of law, to his ancient and more certain title. (Litt. § 659.) The right of entry, which he hath gained by a bad title, fhall be *ipfo facto* annexed to his own inherent good one; and his defeafible eftate fhall be utterly defeated and annulled, by the inftantaneous act of law, without his participation or confent. (Co. Litt. 358. Cro. Jac. 489.) As if A diffeifes B, that is, turns him out of poffeffion, and dies leaving a fon C; hereby the eftate defcends to C, the fon of A, and B is barred from entering thereon till he proves his right in an action: now, if afterwards C, the heir of the diffeifor, makes a leafe for life to D, with remainder to B the diffeifee for life, and D dies; hereby the remainder accrues to B, the diffeifee; who thus gaining a new freehold by virtue of the remainder, which is a bad title, is by act of law remitted, or in of his former and furer eftate. (Finch. L. 194. Litt. § 683.) For he hath hereby gained a new right of poffeffion, to which the law immediately annexes his ancient right of property.

If the fubfequent eftate, or right of poffeffion, be gained by a man's own act or confent, as by immediate purchafe being of full age, he fhall not be remitted. For the taking fuch fubfequent eftate was his own folly, and fhall be looked upon as a waiver of his prior right. (Co. Litt. 348. 350.) Therefore it is to be obferved, that to every remitter there are regularly thefe incidents; an ancient right, and a new defeafible eftate of freehold, uniting in one and the fame perfon; which defeafible eftate muft be *caft upon* the tenant, not gained by his own act or folly. The reafon given by Littleton (§ 661.), why this remedy, which operates filently and by the mere act of law, was allowed, is fomewhat fimilar to that given under the article Retainer; becaufe otherwife he who hath right would be deprived of all remedy. For as he himfelf is the perfon in poffeffion of the freehold, there is no other perfon againft whom he can bring an action, to eftablifh his prior right. And for this caufe the law doth adjudge him in by remitter; that is, in fuch plight as if he had lawfully recovered the fame land by fuit. For, as lord Bacon obferves (Elem. c. 9.), the benignity of the law is fuch, as when, to preferve the principles and grounds of law, it depriveth a man of his remedy without his own fault, it will rather put him in a better degree and condition than in a worfe. *Nam quod remedio deftituitur, ipfa re valet; fi culpa abfit.* But there fhall be no remitter to a right, for which the party has no remedy by action (Co. Litt. 349.): as if the iffue in tail be barred by the fine or warranty of his anceftor, and the freehold is afterwards caft upon him; he fhall not be remitted to his eftate tail. (Moor. 115. 1 Ann. 286.) For the operation of the remitter is exactly the fame, after the union of the two rights, as that of a real action would have been before it. As, therefore, the iffue in tail could not by any action have recovered his ancient eftate, he fhall not recover it by remitter.

The determination of the law, according to the doctrine of remitter above ftated, might feem fuperfluous to an hafty obferver; who perhaps would imagine, that fince the tenant hath now both the right and alfo the poffeffion, it little fignifies by what means fuch poffeffion fhall be faid to be gained. But the wifdom of our ancient law determined nothing in vain. As the tenant's poffeffion was gained by a defective title, it was liable to be overturned by fhewing that defect in a writ of entry; and then he muft have been driven to his writ of right, to recover his juft inheritance: which would have been doubly hard, becaufe, during the time he was himfelf tenant, he could not eftablifh his prior title by any poffeffory action. The law, therefore, remits him to his prior title, or puts him in the fame condition as if if he had recovered the land by writ of entry. Without the remitter, he would have had *jus, et feifinam*, feparate; a good right, but a bad poffeffion: now, by the remitter, he hath the moft perfect of all titles, *juris et feifinæ conjunctionem.* Blackft. Com. b. iii.

REMLINGEN, in *Geography*, a town of Germany, in the county of Wertheim; 9 miles E. of Wertheim.

REMNEY, or Rempney, a river of Wales, which rifes in Brecknockfhire, and, after feparating the counties of Monmouth and Glamorgan, falls into the mouth of the Severn, a little below Cardiff.

REMOLADE, in the *Manege*. See Charge.

REMOLLAN, in *Geography*, a town of France, in the department of the Higher Alps, on the Durance; 15 miles S.W. of Embrun.

REMON, a townfhip of Upper Canada, on the St. Laurence; N. lat. 44° 50′.

REMONSTRANCE, an expoftulation, or humble fupplication, addreffed to the king, or other fuperior, to befeech him to reflect on the inconveniencies, or ill confequences of fome order, edict, or the like.

Remonstrance is alfo ufed for an expoftulatory counfel or advice; or a gentle and handfome reproof, made either in general or particular, to apprife or correct fome fault.

REMONSTRANTS, Remonstrantes, a title given to the Arminians, by reafon of the *remonftrance* they made, in 1610, to the ftates of Holland, againft the fynod of Dort, in which they were condemned.

Epifcopius and Grotius were at the head of the Remonftrants. And as the patrons of Calvinifm prefented an addrefs in oppofition to their remonftrance, which they called their counter-remonftrance, they received, in confequence of this, the name of "Counter-remonftrants."

REMONTER, Fr. in *Mufic*, to new-ftring an inftrument.

REMONTOIR, or Remontoire, in *Horology*, is a fpecies of efcapement, in which a fecondary fpring frequently wound up, or a fmall fecondary weight frequently raifed, by means of the maintaining power of a watch or clock, is fubftituted for the maintaining power itfelf, for the purpofe of urging the balance or pendulum, at fhort intervals, by more equable impulfes than can be conftantly effected by the maintaining power alone, as varied by different degrees of friction in the train. When treating of Escapements in general, under their appropriate head, we defcribed three only out of the four claffes, and referved the fourth clafs, denominated *Remontoir*, till we arrived at our prefent article.

The firft remontoir was invented and made by a German artift in 1600, according to Berthoud; but Huygens, who applied one to his marine clock, defcribed it firft in his "Horologium Ofcillatorium," page 17, and, in conjunction with his cycloidal cheeks, it promifed to be a great improvement in his machine; but, as no compenfation had at that time been applied to the pendulum, and, as a pendulum is not calculated for a portable machine, particularly on the fea, the utility of the contrivance remained to be proved by fubfequent artifts. The contrivance under our confideration was a fmall weight, fufpended by an endlefs well-made metallic chain, that was coiled round the crown-wheel of the efcapement, and wound up a fmall fpace, at every vibration of a half-feconds pendulum, by the next wheel, which wheel took its motion from the maintaining power, through the medium of the train, as is ufual in common clocks; a ratchet and click, however, were a requifite appendage, to act in the way that the endlefs cord was applied, in winding up the maintaining power without ftopping the motion of the works; fuch as we have already defcribed in the fifth fection of our article Clock-work. One half of the weight of the remontoir actuated the efcapement wheel during its fmall fall, and the other half was fupported by the wheel that as often raifed it again to its original height, while both parts of the folded chain were ftretched alike by the faid weight. Leibnitz and Dr. Hooke alfo claimed the originality of a fimilar invention, but do not appear to have put it in practice, as Sully afterwards did.

Mr. Harrifon and Mr. Mudge fucceffively applied remontoir fprings, inftead of fufpended weights, to the efcapements of their time-pieces; but, as we have defcribed thefe under our article Chronometer with fufficient minutenefs, it is not neceffary to repeat here what we have there detailed of their conftructions.

Mr. Cumming and Mr. Nicholfon, on the contrary, had recourfe again to weights inftead of fprings in their aftronomical clocks; but as thefe weights did not act during the whole period of the vibration, we have already defcribed them in another clafs, in the 21ft and 38th fections of our Escapements.

After Huygens and Sully, who left no plans of their mechanifm behind them for the advantage of future workmen, who had not accefs to the original machines, Gaudron contrived a remontoir, which performed its office very well, but which was applied in a wrong place, fo as not to produce the defired effect of equalizing the impulfes given to the regulator; for, inftead of being applied to either the balance or balance-wheel, it was made to actuate the wheel preceding the minute-wheel; and, therefore, permitted the irregular friction of a confiderable portion of the train to affect the motions of the balance, which fault was avoided in the conftruction of Harrifon's and Mudge's time-keepers: the former of which had its fecondary fpring wound up eight times in every minute, and the latter had its two remontoir-fprings alternately coiled at every correfponding ofcillation.

Haley's.—In the year 1796, Mr. Charles Haley, of Wigmore-ftreet, Cavendifh-fquare, London, watch-maker, took out a patent for his invention of a new remontoir fpring for a marine time-piece, or chronometer; the fpecification of which is contained in the 6th volume of the Repertory of Arts and Manufactures. *Figs.* 1 and 2, of *Plate* XLI. of *Horology*, exhibit, the firft a perfpective fide view, and the fecond a plan of Mr. Haley's remontoir efcapement, as originally drawn; and we propofe to retain the fame letters of reference as are inferted in the original defcription. The utility of the invention is ftated to confift of its property of communicating an invariable force to the balance, which it does 150 times in the minute, in a train of 9000 beats in the hour. The fame letters of reference apply to both figures, and indicate the correfponding parts, which will mutually illuftrate each other. A B is the potance plate, and T the balance, the pivots of which, P, X, turn in the cock C and potance D; above the balance T is fixed a pendulum fpring S, in the ufual way; on the axis of the verge, below the balance, are placed two fmall fteel collets I and K, by friction, having each a ruby pallet projecting a little way beyond their furfaces. I is called the difcharging pallet, and K the impelled one; which pallets, together with the pendulum fpring, all vibrate with the balance, whenever it is put in motion. E is the balance-wheel of the ufual form, moving juft clear of the potance plate, and having its pivots fupported by the cocks F and G. W V is the axis of the remontoir, which the inventor calls the *renovating* fpring; and the three axes, or arbors, juft defcribed, ftand in the ftraight line in the direction A B. Below the remontoir fpring the round fteel pallet M is fixed, fo as juſt to eſcape touching the ends of the balance-wheel's teeth in its reſting poſition, and the notch cut in this pallet is to receive the impulſe of any tooth of the ſaid wheel that may, at any time, act againſt it, in paſſing the line A B. Juſt above this large pallet is fixed, by friction, another ſmaller pallet N, of ſteel, in the form of a ſnail-piece, and having inſerted into it, near the centre of motion, and at right angles, a ſmall ruby pallet, which points directly to the radial end of the notch cut in the large pallet M. A ſmall collet, twiſted faſt to the axis of the remontoir, juſt above this ſnail-pallet, receives the lower end of the ſpring R, while the upper end is made faſt to a piece in the cock H, near W, in a manner ſimilar to that by which the pendulum-ſpring is fixed. On the arbor of the remontoir, and under the plate A B, is twiſted on a pallet I, which may be called the remontoir's impelling pallet, becauſe it gives motion to the balance by ſtriking the pallet K, which the author alſo called the *impelling* pallet; but is, as we have named it, more properly the *impelled* pallet, becauſe it *receives* the impulſe which pallet I imparts. From this detail of the pallets it is obvious, that whenever the balance-wheel impels the large pallet M, the remontoir-ſpring R, the ſnail-pallet N, together with its ſmall ruby pallet and impelling pallet I, muſt have a contemporary motion, and will deſcribe each its reſpective circle round the common arbor W V.

In *fig.* 2, *a* is a detent-ſpring, fixed by a ſcrew and ſteady pin to the upper face of the potance plate, and pointing directly to the axis of the verge, which it nearly approaches. Its ſhape and mode of being fixed will be better underſtood from an inſpection of *fig.* 3, which gives a ſide view of it, and from which it will be ſeen that it is placed high enough above the plate, to come in the way of the diſcharging pallet I, in each revolution of the latter. Upon the ſide of the ſaid detent-ſpring *a*, next to the balance-wheel, a ſecond, but very ſlender ſpring is pinned, ſo that its projecting end exceeds that of the detent-ſpring, and comes nearer to the balance verge than that of the detent, as repreſented at *m*, in *fig.* 3. To the detent-ſpring is made faſt a ſmall ruby pallet *r*, ſeen alſo in *fig.* 3. The cock *b* is ſcrewed to the potance, and the hole at *i* is tapped to receive the ſcrew *c*, the head of which, being turned towards the centre of the ſnail, forms a banking for the detent-ſpring *a*, when ſtruck by the ſnail-pallet. This ſcrew, *c*, is removed from its due place in the drawing, to avoid confuſion; and for a reaſon, which will preſently appear, this double ſpring *a* may be called the remontoir-detent. On another ſide of the balance-wheel a ſecond detent-ſpring *d* is fixed, pointing towards the centre of the remontoir axis, and forming nearly a right angle with the former detent: this ſecond detent is adjuſted by the ſcrew *y*. The ſhape and ſituation of this ſecond detent, which may be called the locking detent of the balance-wheel, is better ſeen in *fig.* 4, where its ſapphire pallet *s* may be diſtinguiſhed, againſt which the tooth 3 of the wheel is ſuppoſed to be reſting in *fig.* 2. The ſituation of this pallet *s*, as adjuſted by the ſcrew *y*, determines the reſting-places of the teeth 1 and 2, while they are equally free from the edge of the pallet M. The locking detent *d* is likewiſe made faſt by a ſcrew to the upper face of the potance plate; and the ſcrew *f*, placed in the cock *e*, but out of its place in the figure, forms a banking to the ſapphire pallet *s*, while the ſcrew *g*, in a ſmaller cock, limits the excurſion of the detent-ſpring *d* itſelf.

Having deſcribed the various pieces of mechaniſm that compoſe this remontoir eſcapement, we will now proceed to explain its mode of acting. Firſt, let us ſuppoſe all the parts at reſt with the wheel locked by the pallet *s* laſt deſcribed, but that the wheel is ready to move in the direction of the arrow Z, by the action of the main-ſpring, through the train, whenever the ſingle detent *d* is by any force impelled back to its banking. Let it alſo be conceived that, when the ſnail-pallet N is carried by any means in a direction contrary to that of the wheel till it reaches the pallet *r* of the remontoir or double detent-ſpring, the remointoir-ſpring is wound up by ſuch motion, and *vice verſa*, and alſo that when the ſtroke of the ſnail-pallet has driven back this detent to its banking, by ſtriking the ſloped face of the ruby pallet *r*, the detent will inſtantly return by the force of its elaſticity, and the back part of the ſaid ruby pallet *r* will hold the ſnail-pallet locked at its return, till ſome other impulſe ſets it free again; but that when the unlocking takes place, the ſpring of the remontoir, now wound up, returns by its own force to its original ſituation; and that its axis brings back with it its affixed pallets. *Fig.* 1. will be of no uſe in deſcribing the action of this eſcapement, but in *fig.* 2. the parts are repreſented in a ſtate ready to commence motion; the wheel is locked by tooth 3 againſt the ſapphire pallet *s* of the ſingle detent *d*, and the remontoir-ſpring is wound up, and kept locked by the ſnail-pallet, reſting behind the ruby pallet *r* of the double detent: in this ſituation let the balance be wound round in ſuch direction that the diſcharging pallet I may ſtrike the end of the double or remontoir detent outwards, taking both its ſprings along with it, and thereby unlocking the ſnail-pallet; at this inſtant the remontoir-ſpring R begins to return, and brings all its four pallets with it, and during the return, pallet L, which we have called the impelling pallet, gives its ſtroke to pallet K on the verge, which we have called the impelled pallet, and through its medium to the balance itſelf, which now goes on in its oſcillation, till the pendulum or balance-ſpring is wound up; in the mean time the little unlocking ruby pallet, inſerted into the ſnail-pallet near its centre of motion, meets with the extreme end of detent *d*, and drives it back to its banking, thereby ſetting the tooth 3 of the wheel free from the ſapphire pallet *s*; the wheel, being urged by the train, now proceeds till tooth 2 falls into the notch of pallet M, and is checked, experiencing a little recoil; the balance-ſpring, being now wound up, returns, and alſo the wheel winds up the remontoir-ſpring, till it is again locked, by the ſnail-pallet, after its impulſe has driven back the detent: during this action the detent *d* returns by its own ſpring, and locks tooth 4 of the wheel, at the inſtant that tooth 2 eſcapes from the notch of pallet M, and the original ſituation of all the acting parts is now reſtored, except that the motion of the balance is not arreſted, the ſlender ſpring fixed to detent *a* allowing it to paſs in the return, without unlocking the ſaid detent; but when the backward oſcillation is finiſhed, and the balance returns, the ſame operation is repeated; *i. e.* the remontoir detent is unlocked, the pallets on its axis are brought back, the impulſe is next given to pallet K of the balance, to reſtore its loſs of momentum, and laſtly, the wheel is unlocked to wind up the remontoir-ſpring as before.

The obſervation we have to make on this ingenious remontoir eſcapement is this, that on enquiry from good authority we learn, that the theory could never be completely put into practice by the inventor, though he laboured to obtain his object full fourteen years. However well the parts of action were mechanically made, the locking of the remontoir-ſpring was never certain, for the *flirt* given to the ruby pallet *r* by the ſnail-pallet, drove back the detent ſo far, as frequently to enable the ſnail to be brought back by the remontoir-ſpring, before the detent returned to catch it, the conſequence of which was, that the pallets of the remontoir axis were all brought back, and the impulſe vainly expended

pended by pallet L, before the pallet K of the balance returned to its place to receive it. Mr. Hardy, however, has lately contrived a ſpecies of locking that is quite certain, as well as ſafe, which we ſhall preſently have occaſion to deſcribe.

Breguet's.—We have not been able to aſcertain the exact date of the French watch-maker Breguet's invention of a remontoir eſcapement, but as Berthoud has placed it after Haley's in his "Hiſtoire de la Meſure du Temps," we muſt conclude that it is of more recent origin. The mechaniſm is ſo complex, that the deſcription given in the French work is divided into three parts, which plan we propoſe to follow. *Figs.* 5. and 6. of *Plate* XLI. of *Horology*, will ſuffice to explain the different parts of Breguet's remontoir; *fig.* 5. being a plan of the whole, and *fig.* 6. exhibiting a perſpective view of ſuch parts as could not be well underſtood without ſuch repreſentation. The firſt portion of the mechaniſm conſiſts of two wheels of unequal numbers of teeth, with their planes in contact, and revolving on one common arbor concentrically, namely, the wheel B B′, and the wheel D, the firſt having many teeth and a larger diameter, and the ſecond having few, for a reaſon which will appear hereafter: theſe wheels are actuated by a pinion *g*, connected with the train, and having juſt ſo many leaves as there are teeth in the large wheel B B′, contained in the ſpace between two contiguous teeth of the ſmall wheel D; on the arbor of this pinion, near the pivot, is inſerted a fly with unequal arms, repreſented by the letters *i g h* in both figures, the longer arm of which, *g h*, is armed with a piece of ſteel of peculiar ſhape, ſeen in *fig.* 6. A ſpring-detent *r* F, made faſt to the cock at *r*, lies at right angles to the fly, when in a ſtate of reſt, and has a ruby pallet V at about one-third of its length from its interior end, which ſtops the fly by oppoſing its end *h* near *o*, and conſequently prevents the train from urging the double wheel, ſo long as no force unlocks the pallet from the end of the fly; but if any impulſe happen to bend the detent in a direction towards the pinion *g*, then the ruby pallet ſlips through a notch made in the ſteel part of the fly, and the fly makes an entire revolution, while the pinion revolves and urges the large wheel the ſpace of as many teeth as the pinion contains; that is, a ſpace correſponding to the diſtance between two contiguous large teeth in the ſmall wheel, which wheel alſo moves the ſame quantity, before the fly is again oppoſed and ſtopt.

The ſecond portion conſiſts of the following parts; a ſpring G, curved at the interior, or moveable end, ſerves at the ſame time for a remontoir-ſpring, and alſo for a pallet to give the impulſe to the balance; it has conſequently a heel-piece *n*, by which it is urged into a ſtate of tenſion by the ſmall wheel D, at every revolution of the fly, and alſo a ruby pallet *m*, with a locking notch cut in it; *a* H, made faſt at *a*, is a detent-ſpring, placed nearly at right angles to the ſpring G, and having a ſlender ſpring N made faſt to its ſide; this detent-ſpring carries a ſmall ruby *p*, which locks into the notch of the piece *m* in the ſpring G, when this is in a ſtate of tenſion. Another ruby, inſerted into the extreme end of the detent *a* H at *s*, is ſo placed, that the ſlender ſpring N can move from right to left without impediment, but when urged in an oppoſite direction againſt the ruby *s*, it takes the large or detent-ſpring along with it, and unlocks the remontoir-ſpring G, by removing the ſmall ruby *p* from the notch of *m*. The detent-ſpring H has at its extreme end a claw, againſt which the ruby *m* falls when this detent eſcapes back from a tooth of wheel D; and this claw has a pin in it, againſt which the ſlender ſpring N reſts; again, at the extreme end of the ſlender ſpring N are fixed two parallel chamfered plates, ſo contrived, that any preſſure made on the upper ſlope, or inclined edge, will depreſs the ſpring, but a ſimilar preſſure made on the under ſlope will elevate it again, the downward preſſure being employed to diſengage the ruby *m* from the claw, and the contrary.

The third portion conſiſts of the pieces or pallets K and *b*, borne by the ſuperior end of the verge of the balance, and fixed at a quarter of a circle from each other. When the oſcillation of the balance is from right to left, or in the direction from *b* to K, the unlocking pallet piece K, in its motion, bends the ſlender ſpring, and paſſes over it, but as the pallet *b* is placed above the plane of the wheel B B′, and under the ſpring H, this oſcillation from right to left is performed in freedom, except that the ſlender ſpring N requires to be a little bent out of the way; but when the oſcillation is made from left to right, the pin at H preſſes this ſlender ſpring againſt the ruby *s*, the ſpring H then gives way, and bending, allows the ruby *p* to eſcape from the notch at *m*, and the ſpring G, being unlocked, is at liberty to perform its office, which we now proceed to deſcribe.

The action of theſe three portions of the mechaniſm may be thus explained: at the inſtant that the ruby *p*, in the detent *a* H, is diſengaged from the notch at *m* in the remontoir-ſpring G, the pallet *b* of the balance is found pointing towards the common centre of the wheels, and ready to receive an impulſe from the extreme end *q* of the curved part of the remontoir-ſpring G, which end now gives its ſtroke to the balance through the medium of pallet *b*; immediately after which ſtroke, the ſame end *q* proceeds till it falls on the end F of the fly's detent, to which it now gives a puſh, and remains quiet; this puſh unlocks the fly, as has been before explained, and an entire revolution is immediately performed by it, while its pinion *g*, now at liberty to advance, urges on the double wheel, till another tooth in the ſmall wheel, catching the heel-piece *n* of the remontoir-ſpring, puts this ſpring again into a ſtate of tenſion; and the ruby *p*, falling into the notch of *m*, locks it as before, the balance in the interim completing its oſcillations: and in this manner the operation is repeated.

De Lafon's.—In the year 1801, the Adelphi Society for the Encouragement of Arts, &c. rewarded Mr. John de Lafons with thirty guineas for his invention of a new remontoir watch eſcapement, which comes next under our notice. *Figs.* 1 and 2 of *Plate* XLII. of *Horology*, are a plan and ſection of this eſcapement, as given by the inventor in the Society's Tranſactions of the year above-mentioned. In both theſe figures, A is the eſcapement wheel; B, the lever-pallet on an arbor with fine pivots, which has, at its lower end, the remontoir ſpiral ſpring C, fixed with a collar and ſtud in the uſual way; D is the pallet of the verge, having a roller turning in ſmall pivots, for the lever-pallet to act againſt without friction; at E are the pallets for diſcharging the locking, with a roller between, containing a ſmall notch; F is the arm of the locking pallets, continued at the other end beyond the centre of motion, to preſerve the equipoiſe, and having ſtuds and ſcrews for adjuſtment of the banking; *a* and *b* are the locking pallets, being portions of circles faſtened on an arbor, turning on fine pivots at the midway between the pallets; G is the triple fork, at the end of the arm of the locking pallets. In *fig.* 1, tooth 1 of the wheel having caught the interior end of the lever-pallet B, has urged it forwards and wound up the remontoir-ſpring, and the inſtant that the verge pallet D comes nearly in contact with the remote end of the lever-pallet, the diſcharging pallet E, taking one prong of the fork, removes the arm F, thereby relieving the tooth 3 from the convex part of the claw *a*, that locks the wheels.

The

The wheel now advances a little way, juſt enough to allow the interior end of the lever-pallet to paſs back again, as urged by the ſpiral ſpring, while the remote end of the ſaid lever gives an impulſe to the balance, through the pallet D; the tooth 4 is then locked on the concave ſide of the locking claw *b*, and the interior end of the lever-pallet partly ſupports the following tooth; in this ſituation the oſcillation is finiſhed, and on the return of the balance pallet E, ſtriking the prong of the fork in a contrary direction, again unlocks the wheel from claw *b*, while the force of this wheel is partly ſuſpended by the end of the lever-pallet; being now at liberty, the wheel proceeds to wind up the remontoir-ſpring again, till another tooth falls on the claw *a*, now brought inwards, when the operation is completed, and the preſſure of the inner end of the lever pallet againſt its contiguous tooth again relieves the claw *a* from a part of the preſſure of the wheel, and thereby renders the unlocking as eaſy as before, when claw *b* was unlocked. This eſcapement appears to us an improvement on Haley's, both as to its ſimplicity and ſafety of locking, and the inventor propoſes a ſtill further ſimplification, by ſubſtituting a ſtraight remontoir-ſpring for the ſpiral one, particularly in time-pieces intended to remain in a ſtationary ſituation, where the weight of the ſpring would form no objection; but it does not appear that ſuch conſtruction was ever adopted. The ſimplicity of the locking of the remontoir-ſpring by the wheel itſelf, where this ſpring and the maintaining power mutually re-act, requires, as might be foreſeen, an unuſually ſtrong maintaining power, which is, perhaps, one of the greateſt objections to this mode of applying the remontoir; unleſs, indeed, what was remarked by the ſociety's committee be true, that the balance muſt vibrate in a large arc before the piece will continue to perform.

Maſſey's.—Mr. Edward Maſſey, of Hanley, in Staffordſhire, received a reward of fifty guineas from the Adelphi Society, in the year 1803, for his invention of two different clock eſcapements, one of which we have already deſcribed, under our article Escapement, as being without a verge; and the other we ſhall make the ſubject of our preſent ſection. *Fig.* 3. of *Plate* XLII. repreſents ſo much of Maſſey's remontoir eſcapement as is ſufficient to explain all the eſſential parts; in which A is the ſwing-wheel; B, C, are two detached pallets, moving on ſeparate arbors, at oppoſite ſides of the ſwing-wheel; B is ſeen urged by the remontoir-ſpring E, by the aid of a tail-piece fixed on the arbor of pallet B, which receives the action; and the other pallet muſt be conceived to have a ſimilar ſpring and tail-piece, which cannot eaſily be repreſented in the drawing; F is the verge bearing two arms without pallets, which preſs under the pins of the detached pallets, and raiſe them alternately, at each vibration of the pendulum, from the teeth of the ſwing-wheel, which had been previouſly impelled by the maintaining power, and K is the pendulum ſuſpended in the uſual way, and having a crutch to communicate its force to the verge at the moment of withdrawing the pallets. All, therefore, that the pendulum has to do, is, to diſengage the pallets from the teeth of the ſwing-wheel that locks againſt the inclined planes of the pallets; for the remontoir-ſpring then oppoſes the aſcent of the pendulum, and aids its deſcent, by means of the connection between the pins of the pallets and the arms of the verge, which muſt, from the nature of the conſtruction, continue in contact during a large portion of each excurſion of the pendulum. It is not ſtated in the author's account (Tranſ. Adel. Soc. vol. xxi.) at what part of the arc of vibration the pendulum unlocks either of the pallets, but it ſeems to us capable of being made to effect this office at its point of *greateſt velocity*, if it does not do that as now conſtructed. An attention to this particular is of the utmoſt importance in any eſcapement, ſince the natural law of gravity is the leaſt deranged, when any force is given, or taken away, when the pendulum is at the *loweſt point* of its arc, for the velocity it has at *that point* determines the height to which the ball ſhall riſe; but any addition or diminution of the pendulum's momentum, beginning at any other point of the arc, either adds to, or diminiſhes the natural length of the vibration, and injures the iſochroniſm. Beſides, a ſpring commencing both its accelerating and retarding influence at the point of the pendulum's greateſt velocity, acts, not only by a law commenſurate with the law of gravity, but their various forces, thus exerted, are contemporary, and, therefore, act together as one; a conſideration which never ſhould be loſt ſight of in the conſtruction of an eſcapement of any denomination. The principal advantages that the author ſeems to inſiſt on in this eſcapement, are, that the friction is diminiſhed at the acting parts of the pallets, the impulſe being given by a direct *puſh*, without, or with very little, ſliding motion; and that a certain regular momentum is kept up in the pendulum, independently of any variation which may occur in the wheel-work, or in the acting part of the pallets during the ſhort time of unlocking; but, what is the principal object of ſuch a contrivance, he has not ſtated, perhaps not conſidered, how this *certain regular momentum* is, or ought to be, *modified.*—Indeed, in ſpeaking of his other eſcapement without arbors, he ſays, that one of its advantages over this is, that during a *part* of the vibration the pendulum is *diſengaged;* from which remark, it ſhould ſeem, that he thinks the conſtant action of this remontoir-ſpring, however modified, an objection to be avoided.

Antis'.—In vol. xxiii. of the Tranſactions of the Society laſt mentioned, it is ſtated, that Mr. John Antis of Fulneck, near Leeds, ſent this ſociety a model of a new clock eſcapement in 1805, with a correſponding deſcription, for which a reward was voted him of twenty guineas. The model is depoſited in the room at the Adelphi appropriated for the reception of models, but as the deſcription is not publiſhed in the Tranſactions of the Society, nor an engraving given of the model, we muſt infer, that the contrivance either is not new, or is not of ſuch importance as to merit the particular notice that has been given by them to the inventors of like contrivances, who both preceded and followed him. Indeed, in the letters of Mr. Antis to the Society, publiſhed with their account of the rewards, it ſeems that two eſcapements were ſent them, one a *detached* one, and the other, one that "*would equaliſe* the *power* of the *impulſe*," which muſt, therefore, have been of the *remontoir* deſcription; but he confeſſes that theſe contrivances by him "may have been practiſed before." With reſpect to the latter eſcapement, he remarks, what is worthy of being recollected by clock-makers in general, that, by its means "a ſpring-clock will be as perfect as one which goes by weight, and more ſo if the latter has no remontoir." Should any of our readers have a wiſh to ſee and examine Mr. Antis' productions, which, he acknowledges, are done in a rough manner, and under diſadvantageous circumſtances, but which may not be the leſs ingenious on that account, there will be no difficulty in gaining admiſſion to the model room, where the original work is preſerved with a view to public inſpection, provided the applicant be properly introduced.

Mendham's.—It frequently happens that conſiderable improve-

improvements are made in mechanical contrivances, by men whofe principal employment has no connection with the art to the improvement of which they contribute; this was probably the cafe with Mr. Antis, and is confeffedly fo with Mr. Mendham, who was rewarded with the filver medal of the Adelphi Society, in the year 1807, (fee vol. xxv.) for a remontoir efcapement for a chronometer, which next offers itfelf for our defcription. *Figs.* 4, 5, and 6, of *Plate* XLII. are copied from the plate given by Mr. Mendham, *fig.* 4. being a fection of the whole efcapement, *fig.* 5. a plan of the wheel and locking pallet, and *fig.* 6. a detached view of the pallets and their common arbor. The letters *a a*, in *fig.* 4, are the two plates of the frame that contain the works; *b* is the balance, nearly of the ufual fhape and fize; *c* is the pallet that acts with the wheel, and *d* its arbor; *e* is the locking fingle fpring; and *f* is the unlocking pallet in the form of a pin, attached to *e*, and feen better in *fig.* 6. At the lower end of arbor *d* is placed *g*, the remontoir-fpring, that gives force both to the fmall pallet *f*, and alfo to the perpendicular pin *h*, that forms a part of the pallet *c*. The arbor *d* does not afcend above the upper plate of the frame, but the pin *h* does, and the plate being formed, as we fuppofe, like a rim, *h* is permitted to move in the vacant fpace within the rim, and fufficiently high to fall in the way of the finer pin *l*, inferted into and under the balance. The balance *i* has its verge immediately over the upper pivot of arbor *d*, point to point nearly, fo that the motions of the balance-pin *i*, and of the pin *h*, that impels it, may be concentric. The cock *k* fupports the upper pivot of the verge, and alfo holds the outer end of the balance or pendulum-fpring. The action of thefe parts may be thus explained; before motion is given to the balance, we muft conceive its pin *i* to be in contact, or nearly in contact with the pin *h* of the pallet *c*, and it muft be remembered, that the wheel refts on the pallet during the vibration of the balance: fuppofe now that the remontoir-fpring *g* is in the act of being wound up by the balance-wheel, as actuated by the train; and that the pin *i* of the moving balance has kept in contact with the impelling pin *h*, borne by the arbor of the remontoir, it is evident, that the force of the remontoir-fpring is here oppofed to the momentum of the balance and at laft ftops it, thereby forming a banking of an unlimited extent; but the tooth of the wheel in contact with pallet *c*, at the point of fhorteft radius, affifts to oppofe or wind up the faid fpring during a fpace of one-fifth of a circle, till the tooth has paffed and the wheel is locked; on the return of the balance the remontoir-fpring exerts all its force on the balance, but without a jerk, the pins *i* and *h* being already in contact, till it comes to the ftop; the balance then maintains its motion, and the fmall pallet *f* having unlocked the wheel by forcing out the detent, the next tooth of the wheel falls on the pallet *c*, and waits the return of the balance, when the fame operation is repeated.

Mr. Ramfay of Iflington was confulted on the merits of this efcapement, and, on confidering its properties, he gave a written report to this effect; that the impulfe is here given to the balance without friction, exactly as in Mudge's chronometer; and that the remontoir is wound up by the maintaining power in a fimilar way, except that the fhape of Mudge's tooth limited the quantity of tenfion of the fpring, which here depends on the amount of the maintaining power; but that this efcapement, having but one remontoir-fpring, is more fimple than Mudge's, and allows an unlimited arc of vibration, which advantages compenfate the foregoing difadvantage in the fhape of the tooth; and laftly, that it is fuperior to the detached efcapement, inafmuch as that it gives the impulfe without friction.

G. Prior's.—The filver medal and twenty-five guineas were voted to Mr. George Prior, junior, of Otley, in Yorkfhire, in the year 1809, by the Adelphi fociety (vol. xxvii.) for his invention of a new clock efcapement, in which an impelling (not however called a remontoir) fpring actuates, or profeffes to actuate, the pendulum at each alternate vibration. The account, particularly of the action, as printed in the fociety's Tranfactions, feems to us fo extraordinary, that we beg leave to tranfcribe it verbatim, in order to make fome remarks on it, that may enable the reader to judge of the efcapement's peculiar qualities, or at leaft of the manner in which they are defcribed. *Fig.* 7. of *Plate* XLII. already referred to, contains enough of this efcapement to anfwer the purpofe of the defcription in queftion, and therefore we will omit the references to *fig.* 1. in the original plate, and attend to its *fig.* 2. only. "*Fig.* (7) is a back view, which is fuppofed to be taken from behind the clock; *a* reprefents the axis of the fwing-wheel, or laft wheel of the train of the clock; *b d* is the fwing-wheel fixed upon it, having thirty ferrated teeth; it is turned round, in the direction from *b to d*, by the maintaining power of the clock; *g* is a fpring-detent, which locks againft one of the teeth of the fwing-wheel, and this prevents its running down by the action of the maintaining power; *h* is another fpring-detent, which is called the impelling fpring; when left at liberty, it unlocks the former, by pufhing againft the end of the fmall arc *e*, faftened to the detent *g*. and thus removing the end of the detent which obftructed the wheel's motion; *l* is the rod of the pendulum, fufpended by a cock fcrewed to the back plate of the clock; a fmall piece of brafs, *k*, projects at right angles from the impelling fpring *h*, fo as to intercept the pendulum-rod in its vibration, and at this place a fmall fcrew is put through the pendulum-rod *l*, the point of which moves the impelling fpring back: a fmall pin is fixed to the frame, in a line between the point of fufpenfion of the pendulum, and the centre of the fwing-wheel, againft which the impelling fpring ftops when at liberty.

"Suppofing the pendulum to be vibrating backwards and forwards, and the wheel locked as in the figure, the pendulum fwinging from *m* to *n*, the impelling fpring *h* follows by its elafticity, until the pendulum *l* arrives at its perpendicular (or loweft point of its arc); at this period the impelling fpring comes *to reft* againft the end of the arc *e*, which it *pufhes back*, fo as to releafe the tooth of the wheel from the detent-fpring *g*; the wheel now moves round a very fmall fpace before it meets the end of the impelling fpring *h*, and *is ftopped thereby*; in the mean time the pendulum continues its motion the extent of its vibration towards *n*, when it returns, and arriving at the *perpendicular*, it meets the *impelling fpring h*, and *carries it along with it*, until the tooth of the wheel which refts againft it efcapes from the end of it, and another tooth of the wheel comes to reft againft the fpring-detent *g*. The fucceeding vibration of the pendulum repeats the fame operation." This is the whole account, from which the reader is induced to believe that the pendulum, and impelling fpring *h*, act and re-act on each other *ad infinitum*, without any aid from the maintaining power through the medium of the wheel, which is never faid to raife, or otherwife to move the impelling (or remontoir) pallet, in order that it may, in its turn, impel the pendulum by its acquired force. Again, it is faid, the impelling fpring unlocks the detent *g* when it arrives at the perpendicular, or nearly, if not quite, at the point of its quiefcence, where it has *no force*, and from that point, not the

the wheel, but the pendulum unbends it into a ſtate of tenſion, to reſume its operation; that is, the pendulum raiſes the ſpring, that the ſpring may drive the pendulum back again; and thus the vibrations are maintained without the aid, and conſequently without the neceſſity, of either a maintaining power or train; and what is equally extraordinary, the impelling ſpring locks the wheel by its *reſiſtance*, near the perpendicular line (within the ſpace of one tooth), where it has almoſt the ſmalleſt force, or nearly the ſame ſmall force that it has when it *unlocks* the *detent*. According to this account, even ſuppoſing the action of the wheel on the remontoir pallet to be *omitted*, the pendulum is under the influence of the impelling pallet during nearly the whole of one excurſion, and free from it in the other. The model, however, is ſaid to be preſerved in the ſociety's room, and will explain itſelf.

G. Prior's improved.—Mr. George Prior, jun. again preſents an improved remontoir eſcapement for a clock to the ſociety we have repeatedly had occaſion to name in this article, in the year 1811 (vol. xxix.), and again receives a reward at their hands, of twenty guineas, for his improvement. The deſcription given of this eſcapement, and of its action, is ſufficiently clear, and the alteration made in the conſtruction is in many reſpects an improvement, though we ſhall take occaſion to ſhew, in our remarks on it, that it is ſtill liable to objections. In the plate laſt referred to, *fig.* 8. contains the original *fig.* 1, which will explain the account with ſufficient preciſion. "The ſwing-wheel A," ſays the author, "has thirty teeth cut in its periphery, and is conſtantly urged forwards by the maintaining power; C, D, are two ſpring-detents, catching the teeth of the wheel alternately; theſe are, at the proper intervals, unlocked by the parts marked 2 and 3 upon the pendulum-rod H, intercepting ſmall pins *a*, *b*, projecting from the detents, as it vibrates towards the one or the other; E is the renovating or remontoir-ſpring, fixed to the ſame ſtud, F, as the detents; it is wound up by the higheſt tooth of the wheel, its poſition, when unwound, being ſhewn by the perpendicular dotted line. This being the caſe, ſuppoſe a tooth of the wheel caught by the detent D, which prevents the wheel from moving any further, and keeps the renovating ſpring from eſcaping off the point of the tooth; in this poſition the pendulum is quite detached from the wheel: now if the pendulum be cauſed to vibrate towards G, the part of it marked 2 comes againſt the pin *b*, projecting from the renovating ſpring E, and puſhes this ſpring from the point of the wheel's tooth; on vibrating a little further, it removes the detent D, which detained the wheel, by the part 3 ſtriking the pin *a*, which projects from the detent; the maintaining power of the clock makes the wheel, thus unlocked, to advance, until it is detained by a tooth reſting upon the end of the detent C, on the oppoſite ſide; by this means the renovating ſpring will be clear of the tooth of the wheel as it returns with the pendulum, and gives it an impulſe by its pin *b* preſſing againſt the part 2 of the pendulum, until the ſpring comes to the poſition ſhewn by the dotted line, in which poſition it is unwound, and reſts againſt a pin fixed in the croſs-bar of the plate; the pendulum continues vibrating towards I, nearly to the extent of its vibration, when the part 1 meets the pin in the detent C, and removes it from the wheel and unlocks it; the maintaining power now carries it forward, puſhing the renovating ſpring E before it, until another tooth is caught by the detent D, which detains the wheel in the poſition firſt deſcribed." Agreeably to this deſcription, the pendulum is oppoſed in its aſcent, and accelerated in its deſcent, in one of its excurſions from the centre, or perpendicular line, by both the impelling ſpring E, and detent D, after it is unlocked, though not the whole diſtance; but is alternately accelerated and retarded in the other excurſion by the detent C alone, and only after the unlocking; theſe unequal checks, given at different parts of the arc of vibration, we apprehend, are by no means favourable to the natural iſochroniſm of the pendulum.

Hardy's.—Mr. Hardy, chronometer-maker, of Coppice-row, Clerkenwell, London, whoſe ingenious improvements in clock and watch-making have placed him high in public eſtimation, on contemplating Mr. C. Haley's failure in the locking of his remontoir detent, contrived a remedy which fully anſwers its purpoſe, and which, on that account, merits our particular notice.

Fig. 7. of *Plate* XLI. of *Horology*, repreſents the plan of Hardy's new remontoir eſcapement, which, though it appears to differ conſiderably in conſtruction from Haley's, yet reſembles it ſo much in its action, as well as principle, that we will put the ſame letters of reference to the ſame correſponding parts, in order that the reader who has peruſed our deſcription of Haley's remontoir with attention, may the more clearly comprehend our deſcription of Hardy's, and perceive in what the improvement conſiſts. As in Haley's conſtruction, T T repreſents the balance, or rather the place of the balance not ſeen; E the eſcapement, or balance-wheel; P the pivot of the verge; S the balance-ſpring, ſuſpended as uſual; K the impelled pallet; I the unlocking pallet of the remontoir; N the remontoir detent, or locking pallet, on the ſame axis with *a*, the arm of the ſlender or unlocking ſpring, which lies parallel with it; *n* the cock, taking the pivot of the remontoir detent's arbor, and alſo the upper end of its ſpiral ſpring; *c* the head of the banking ſcrew, and *i* its ſtud; H the cock that takes the pivot of the remontoir, or cylindrical ſpring at W, and alſo one end of the ſaid ſpring, repreſented by the ſmall circle at R; L is the impelling lever or pallet, for giving motion to the pallet K of the balance; M is a lever, inſtead of the notch in Haley's large circular pallet, by means of which the wheel winds up the ſpring R of the remontoir; O is a lever, in place of the ſmall ruby unlocking pallet of Haley, fixed to the ſnail; *d* is the ſpring-detent of the wheel, and *s* its ruby, or ſapphire pallet, on which the wheel is locked, *f* and *g* being the banking ſcrew and its ſtud, and *y* the place where it is fixed by a ſcrew on the potance plate; and laſtly, the ſectoral piece Q, in which the improvement chiefly conſiſts, is the addition introduced for rendering the locking of the remointoir-ſpring, when wound up, both certain and ſecure. The acting faces of the pallets *s*, M, K, N, and of the circular portion of Q, are of ruby, or other precious ſtone nicely poliſhed, and are properly ſhaped for their reſpective offices. From this deſcription of the mechaniſm before us, it will be perceived that the double ſpring *a*, and the detent with a claw pallet at N, are both faſt to the arbor of the ſpiral ſpring, which gently preſſes the detent at all times down upon the ſectoral piece Q, thereby preventing its being thrown back from its poſition for locking, as was the caſe with Haley's remontoir detent. It will alſo be ſeen that the arbor W, of the remontoir-ſpring R, has the ſaid ſectoral piece, the impelling lever L, the lever M impelled by the wheel, and the diſcharging lever O, all faſt to it at different heights, the two firſt being above, and the two laſt below, ſo that when one of theſe four pieces is moved out of its firſt ſituation by any external force, they all move together, as do alſo the remontoir detent N and its ſpring *a* on their common arbor, and as do likewiſe the pallets K and I on the verge of the balance. Theſe particulars being underſtood, and that levers in Hardy's conſtruction are uſed ufed for pallets in feveral inftances, we may proceed to explain the action of the different parts, and to fhew how they produce the defired effects of producing equable impulfes on the balance at all times, and of effecting certain and fecure locking of the remontoir-fpring. In the figure before us, tooth 1 of the wheel has juft proceeded far enough, by the action of the main-fpring and train, to wind up the remontoir-fpring, and its detent N, urged by its own fpiral fpring againft the curved face of the fectoral piece, after fliding fmoothly along it, has locked it; that is, by oppofing it at right angles, prevents its return, which would take place when the wheel leaves the arm M, or, which is the fame thing, when the remontoir-fpring, on the fame arbor with this arm, is wound up. The balance is now fuppofed to have commenced its motion, carrying the pallets K and I outwards from the wheel, but the fmall pallet I has not yet arrived at the flender fpring of the remontoir detent, though it is approaching it; the flender fpring, however, foon yields to the outward impulfe of this fmall pallet, without difturbing its arm or the detent N, therefore the remontoir-fpring remains locked: at the return of the balance, which takes place when its fpring is wound up, the faid little pallet I difplaces not only the flender fpring but its arm alfo, which lies next towards the wheel, the one not being liable to move in this inward direction without the other; the confequence is, that the detent N is now lifted by its connection with the arm of the flender fpring, and at that inftant the remontoir-fpring, being wound up, and at liberty to act, throws back the fectoral piece Q nearly its whole breadth, but not quite, for the claw of the detent in queftion refts on the curve of the fector during the motion we have defcribed, till the unlocking lever O ftrikes the end of the fingle detent-fpring *d*, and forces the ruby pallet *s* out of the wheel, which wheel inftantaneoufly refumes its motion from the train, and meeting with lever M winds up the remontoir-fpring a fecond time; in the mean time the impelling lever L has given its impulfe to the pallet or lever K, and confequently to the balance, which has thus had its momentum increafed; and on its returning vibration exactly the fame procefs is repeated. Thus the force of the maintaining power is expended in winding up at each alternate ofcillation the remontoir-fpring, which fpring, fo reinforced, impels the balance in its turn by quantities of force that are always the fame, whatever may be the irregularities of the force tranfmitted through the train that winds up the remontoir-fpring; therefore, properly fpeaking, the remontoir-fpring is the maintaining power that reftores, at each alternate ofcillation, the lofs of momentum that the balance has experienced from the refiftance of the air, and friction of the parts in action. This efcapement is, notwithftanding, of the detached kind, feeing the balance performs the greateft part of its ofcillations without any connection of even the auxiliary force derived at intervals from the remontoir-fpring; and a chronometer of this conftruction, made by Hardy for his royal highnefs the duke of Suffex, anfwers the maker's moft fanguine expectation, and will probably become a model for other makers when its merit is proved, and made public. The fame artift has made feveral experiments on the fame principle, with this difference, that the remontoir-fpring is retained by the lever refting on the tooth of the wheel, in place of being locked by the fectoral piece, as in the one before us.

Befides the preceding efcapement, Hardy invented one for the aftronomical clock he made for the Royal Obfervatory at Greenwich, which at firft fight appears to refemble Maffey's and Prior's improved one, with fpring pallets, but on clofe examination we difcovered that it has the following defirable properties peculiar to itfelf: 1ft, it gives the impulfe not only from remontoir-fprings, but ftrikes and unlocks the two feparate detents alternately, at the inftant when the pendulum has the *greateft velocity*; and, 2dly, the accelerating and retarding power imparted to the pendulum co-operates with the force of gravity, thereby deranging the natural law of gravity as little as poffible. We feel not at liberty to enter more minutely into the defcription of this efcapement, becaufe we underftand its inventor propofes giving an account of his machine himfelf, to be read before the Royal Society, as conftituting the companion to Troughton's tranfit circle, already defcribed by the aftronomer royal. We have permiffion, however, to fubjoin the rate of the clock in queftion for three quarters of a year, as taken at the Royal Obfervatory, which will afford the beft proof of its pretenfions to public notice. We have further to add, that the inventor has applied the fame principle of movement to a chronometer of a large fize, in which the balance has two metallic rods to adjuft it for temperature, in place of the metal being fluxed on the rim of the balance, as is common. See COMPENSATION.

Trial of Mr. Hardy's clock at the Royal Obfervatory at Greenwich in the year 1811.

	Daily Rate.	Mean of Thermometer.
April 12 to May 13 - -	— 0.86″	61°
May 13 to June 9 - -	— 0.74	63
June 17 to July 12 - -	— 0.74	64
July 18 to Auguft 17 - -	— 0.83	68
Auguft 17 to September 14 -	— 0.77	65
September 14 to October 4 -	— 0.61	60
October 17 to November 17 -	— 0.60	51
November 17 to December 10	— 0.50	46
December 10 to December 30	— 0.47	39

From the above ftated authentic document it appears, that for the nine months of trial, and in oppofite extremes of temperature, the daily rate never varied quite *four-tenths* of a fecond; and when the quantity of mercury proper for the compenfation of the pendulum is exactly afcertained, it may be expected that the performance will be ftill more accurate; feeing that the deviation in the rate depends evidently on the change of temperature, and not on the efcapement.

REMORA, in *Natural Hiftory*, the *fucking-fifh*; a little fifh, refembling a herring, called by the Greeks *echeneis*, famous for fticking to the fides of fhips. It belongs to the genus of *echeneis* and clafs of *thoracici* in the Linnæan fyftem.

Its characters, according to Artedi and Linnæus, are thefe: the branchioftege membrane on each fide contains about ten bones; the head is thick, depreffed, naked, and marked on the upper fide with tranfverfe rough ftriæ; the body is oblong, roundifh, and naked, but fomewhat compreffed; the back-fin is oblong, and placed very far toward the tail; its under jaw is longer than its upper; it has a great number of teeth in both jaws; the colour of its body is hoary, and it has feven fins; two pectoral ones, two ventral ones placed farther from the fnout than the pectoral ones, one at the anus, one on the back, and one at the tail; the ftriæ of the head are from eighteen to twenty-four in number, they are rough and tranfverfe, but are divided as it were into two feries by a middle longitudinal line. By means of thefe ftriæ or ridges the fifh can fix itfelf to any animal

animal or other ſubſtance, and has often been found adhering to the ſides of ſhips and the bodies of ſharks, &c.

Linnæus enumerates two ſpecies of the echeneis; the remora and neucrates: the former has a forked tail, and eighteen ſtriæ on the head; the latter has an entire tail, which is longer than that of the former, twenty-four ſtriæ, a larger body, and ſharper fins. They are both inhabitants of the Indian ocean. The remora is much talked of by the ancients, who, as we find from Pliny, lib. ix. cap. 25. lib. xxxi. cap. 31. unanimouſly believed it had the force to ſtop a veſſel in full ſail, or a whale in ſwimming; and hence called it *remora, a remorando*. (See Ælian's Hiſt. de Animal. lib. ii. cap. 17. Plutarch. Sympoſ. lib. ii.) But Mr. Cateſby obſerves, that even ſeveral of thoſe fiſhes together can do no more than ſhells or corals, and other foulneſſes of the ſame bulk, which make a ſhip ſail ſomewhat the ſlower. And in the ſame manner only they may be ſome ſmall hindrance to a whale. The author laſt mentioned aſſures us he has taken five of them off the body of a ſhark. Vide Phil. Tranſ. N° 438. p. 113.

REMORA, among *Surgeons*, is alſo an inſtrument uſed for ſetting broken bones.

REMORA *Mutiani*, in *Natural Hiſtory*, a name given by ſome to the genus of ſhells called *concha venerea*, and *porcelana*. See PORCELAIN *Shell*.

REMOTION, REMOTIO, in *Rhetoric*, the ſame with what is otherwiſe called *metaſtaſis*.

REMOVAL *of the Poor*. See POOR.

REMOVELLE, in *Geography*, a town of France, in the department of the Voſges; 5 miles E. of Neufchateau.

REMOVING *Obſtructions to Tillage*, the means of removing ſtones and any other ſubſtances that may be in the way of the plough.

The operations which are to be performed in theſe intentions are of ſeveral different kinds, as the removing of various ſorts and ſtates of ſtony matters, both from above and below the ſurface of the lands; the eradicating and deſtroying different kinds of woody materials of the tree, root, and plant ſorts, the taking away of the ſuperabundant wetneſs; the deſtruction of many aquatic vegetables, and ſome others. See LAND, STONE, TILLAGE, and WOOD.

REMOULIN, in the *Manege*, is uſed to denote a ſtar upon a horſe's forehead.

REMOULINS, in *Geography*, a town of France, in the department of the Gard, and chief place of a canton, in the diſtrict of Uzés; 7 miles S.E. of Uzés. The place contains 905, and the canton 4758 inhabitants, on a territory of 135 kiliometres, in 8 communes.

REMOUNT, in *War*. *To remount the cavalry*, or *dragoons*, is to furniſh them with freſh horſes, in lieu of ſuch as have been killed or diſabled in the ſervice.

REMPHAN, in *Antiquity*, the Egyptian name for the planet Saturn. Some think that remphan was the moon, others Mercury and Mars, and others the ſun. See CHIUN.

REMPLY, in *Heraldry*, ſomething *filled up*. The term is chiefly uſed to denote, that the chief is quite filled up with a ſquare piece of another colour, leaving only a bordure of the proper colour of the chief about the ſaid piece.

REMPORETTY, in *Geography*, a town of Hindooſtan; 30 miles N. E. of Travancore.

REMS, a river of Wurtemberg, which runs into the Neckar, 4 miles N.W. of Waiblingen.

REMSA, or REMISSAM, a town of Saxony, in the lordſhip of Schonburg; 2 miles N.N.E. of Glauchau.

REMSCHEIDT, a town of the duchy of Berg; 2 miles S.W. of Lennep.

REMSEN, a townſhip of America, in Oneida county, New York, E. of Leyden and adjoining it.

REMUNGOL, a town of France, in the department of the Morbihan; 7 miles S. of Pontivy.

REMURIA, among the Romans, a feſtival inſtituted in honour of Remus by his brother Romulus. See LEMURIA.

REMUZAL, in *Geography*, a town of France, in the department of the Drôme, and chief place of a canton, in the diſtrict of Nyons; 6 miles N.E. of Nyons. The place contains 514, and the canton 3724 inhabitants, on a territory of $272\frac{1}{2}$ kiliometres, in 17 communes.

REMY, a town of France, in the department of the Oiſe; 6 miles N. of Clermont.

REN, a town of Ruſſia, in the government of Novgorod; 16 miles S.E. of Uſtiuzna.

RENAISON, a town of France, in the department of the Rhône and Loire; 6 miles W. of Roanne.

RENAIX, a town of France, in the department of the Scheldt, and chief place of a canton, in the diſtrict of Audenaerde. The place contains 9499, and the canton 14,683 inhabitants, on a territory of 70 kiliometres, in 6 communes.

RENALIS, RENAL, in *Anatomy*, an epithet applied to the parts belonging to the kidney; as to the artery and vein of the organ, alſo called *emulgent*, of which the former comes from the aorta, the latter joins the inferior vena cava; ſee ARTERY and VEIN: to the plexus of nerves derived principally from the ganglia of the great ſympathetic; ſee NERVE: and to the ſmall bodies placed above the kidnies, called the *renal capſules*. See alſo KIDNEY.

RENALIS *Lapis*, in *Natural Hiſtory*, the name given by many authors to a ſort of ſiderochitum, or cruſtated ferruginous body of that kind, containing a nucleus of a different matter from that of the cruſts. It is found about Prague, and in ſome other places, lying near the ſurface in ſtrata of a yellow clay. Its uſual bigneſs is that of a ripe peach, and its cruſts are of a duſky ferruginous brown colour: and its internal nucleus of a pale yellowiſh-green, compoſed of a marley earth, and uſually of a kidney-like ſhape, whence its name.

RENASSAU, in *Geography*, a town of Hindooſtan, in Dowlatabad; 114 miles N.W. of Hydrabad. N. lat. 18° 30′. E. long. 79° 10′.

RENATHIA, a town of Aſiatic Turkey, in Caramania; 10 miles S.W. of Satalia.

RENAU D'ELISAGARAY, BERNARD, in *Biography*, a diſtinguiſhed engineer and naval architect, was born in the province of Bearn, in the year 1652. He was at an early age inſtructed in the mathematical ſciences, and was obſerved not to read a great deal, but to think moſt profoundly, and as he advanced in years, he was capable of thinking upon the moſt abſtruſe ſubjects, as well in the midſt of company, as in the cloſet. One of the firſt books that attracted his attention was Malebranche's "Reſearche de la Verité," and, it is ſaid, it made ſuch an impreſſion upon him, that nothing could efface it through the whole of life. It gave him a full conviction of the truths of religion, and preſerved his morals pure and uncorrupted. In 1679 he was placed with the count de Vermandois, admiral of France, as his inſtructor in naval affairs. When, by the royal command, conferences were held to determine upon a plan for bringing to perfection the conſtruction of veſſels, Renau was called upon for his opinion; and at length the ſyſtems of Du Queſne and that of Renau were alone left for conſideration, and to the honour of Renau, then young and almoſt unknown, his plan was adopted, and he himſelf was ſent to Breſt and the other ports to put it in execution.

In 1680, the Algerines having declared war againſt France, Renau propoſed the bombardment of Algiers, for which purpoſe he conceived the idea of bomb-veſſels, which were as yet unknown. This was at firſt regarded as viſionary; but reliance being placed on his talents, he was permitted to make the trial, and he brought five of theſe veſſels before the town, where, under the command of Du Queſne, the bombardment was executed with complete ſucceſs. In 1684 he was employed, as engineer, at the bombardment of Genoa; from this place he went to join Vauban, who was fortifying the frontiers of Flanders and Germany, and he contracted an intimate friendſhip with that great man. In 1688 he accompanied Vauban to the ſiege of Philipſburg, and afterwards conducted, or was preſent, at ſome other ſieges; yet in the midſt of theſe active ſervices he found leiſure to attend to his ſtudies, and publiſhed in 1689 his "Theorie de la Manœuvre des Vaiſſeaux:" ſome of the propoſitions in this work were conteſted by the celebrated Huygens. In this ſame year he endeavoured to prove, by argument, that the navy of France might be rendered capable of making head againſt that of England and Holland united, and his obſervation produced ſuch an effect upon the government, that an order was made to change all the 50 and 60-gun veſſels, on the ſtocks, into ſhips of a higher rate. About the ſame time he invented a new ſeries of naval evolutions, ſignals, and orders of battle. His merits were well underſtood by the government, who rewarded him with a penſion, and conſiderable rank in the ſervice. He was now ſent to Breſt for the purpoſe of inſtructing the naval officers in his newly invented evolutions, &c. He met with an oppoſition, which is not uncommon in endeavouring to change old eſtabliſhed cuſtoms. Of his opponents, two of the moſt diſtinguiſhed were put under arreſt and broke, though he did his utmoſt to prevent the puniſhment being carried to that extremity. He afterwards ſerved under Vauban at the ſiege of Namur, from thence he repaired to St. Malo after the battle of La Hogue, to ſave the relics of the French fleet which had taken ſhelter there. Having conſtructed a veſſel of 54 guns upon his own plan, Renau put to ſea with the view of intercepting two rich Engliſh Eaſt Indiamen, one of which he captured after a deſperate engagement. Among the booty were ſome packets of diamonds, which he thought of too great value to be claimed by himſelf, though the naval cuſtoms would have juſtified him in it, and he carried them to the king, who accepted the prize, and remunerated the captor with an annuity. When Philip V. ſucceeded to the crown of Spain, he ſent to his grandfather, Lewis XIV., to requeſt that he might have Renau to direct his engineers in fortifying his moſt important towns. He found means to render the crown of Spain the moſt important ſervices, and was, in 1704, employed in the ſiege of Gibraltar, which, it has been aſſumed by the French biographer, was about to ſurrender, when it was relieved by the Engliſh fleet. To the diſgrace of the court of Spain, whoſe intereſts he had effectually promoted, and in whoſe cauſe he had expended his own property, he was ſuffered to return to France with a ſingle piſtole in his pocket, though his Catholic majeſty had given him the title of lieutenant-general of the armies of Spain. The high reputation which Renau had acquired as an engineer, cauſed the grand-maſter of Malta to requeſt that he might be ſent to that iſland on an alarm of an invaſion, which was readily granted. Soon after this Lewis XIV. died, and the duke of Orleans ſucceeded to the regency, who appointed Renau to be counſellor of the marine council, and grand-croix of St. Louis. He died of a dropſy in 1719, and his death was, like that of La Trappe, in ardent aſpirations after another life: "What a difference," he exclaimed, "from one moment to the following! I am going to paſs in an inſtant from the thickeſt darkneſs to perfect light." He had been twenty years an honorary member of the Academy of Sciences, and was among the firſt after that claſs was inſtituted.

RENAUDOT, Eusebius, a learned writer on the eccleſiaſtical hiſtory and antiquities of the Eaſtern church, was born at Paris in 1646. He was educated at the Jeſuits' college, and entered the congregation of the oratory when he was about 19 years of age, though he had no intention of entering into holy orders, or to the taking any eccleſiaſtical degree. He was particularly attached to the ſtudy of the oriental languages, in the knowledge of which he far excelled almoſt all his contemporaries; and he applied with ſucceſs to the ſtudy of ſo many other tongues, that he was ſufficiently maſter of ſeventeen different languages, to be able to ſpeak the greater number of them with facility. He became well known at court, where his genius, his talents, and his politeneſs, made him much eſteemed and admired. Here he was noticed by M. Colbert, who was deſirous of eſtabliſhing printing-preſſes for the oriental languages at Paris, and conſulted Renaudot upon the ſubject, as a perſon who might ably contribute to render ſuch an eſtabliſhment uſeful to the ſtate as well as the church. To engage his aſſiſtance, he promiſed him the reverſion of the poſt of keeper of the king's library; but the miniſter died before the place became vacant. He received a ſimilar promiſe from the archbiſhop of Rheims, and was again diſappointed. He was, however, employed by the king in various confidential concerns of great importance relating to the affairs of Rome, England, Spain, &c. So much was his time occupied by theſe engagements, that he almoſt entirely diſcontinued his favourite ſtudies. In the year 1689 he was received into the French Academy, and in 1692 into the Academy of Inſcriptions and Belles Lettres. He found a patron in the cardinal de Noailles, archbiſhop of Paris, whom he accompanied to Rome in the year 1700, and into the conclave which elected Clement XI. to the papal dignity. While he remained in that city, the collections of the Vatican furniſhed him with new matter relating to the oriental churches, and revived an intention, which he had long before encouraged, of preparing for publication ſome pieces which ſerve to illuſtrate their hiſtory and opinions. In this deſign he was aſſiſted by the new pope, who perſuaded him to remain in Rome ſeveral months after the departure of cardinal de Noailles. His holineſs would gladly have conferred upon him ſome valuable benefices, but he refuſed to accept of any thing beyond a ſmall priory. The abbé Renaudot afterwards went to Florence, where he met with moſt flattering reception from the grand duke, who aſſigned him apartments in his own palace, loaded him with preſents, and on his departure directed that he ſhould be conveyed on board one of his own veſſels to Marſeilles. At Florence, likewiſe, he was made a member of the Academy de la Cruſca. Soon after his return from France, he was rouſed by an attack upon father Nicole's "Perpetuity of the Faith of the Catholic Church reſpecting the Euchariſt;" and in 1708 he publiſhed "A Defence of the Perpetuity of the Faith againſt the Calumnies, &c." He afterwards entered more fully into the ſubject which he defended, and diſplayed all his erudition and ingenuity in endeavouring to ſhew the conformity between the doctrine of the Greeks, and all the oriental Chriſtians, with that of the Latin church. What he wrote upon the ſubject extended to two vols. 4to. which were publiſhed in 1711 and 1713, by way of of ſupplement to father Nicole's work. During the regency of the duke of Orleans he made frequent efforts to obtain his encouragement of the plan for eſtabliſhing printing-preſſes for the oriental tongues, and was promiſed, but never obtained effectual ſupport. The latter years of his life he ſpent in completing numerous very learned and important publications, among which may be mentioned, "Hiſtoria Patriarcharum Alexandrinorum Jacobitarum:" "Liturgiarum Orientalium Collectio," in 2 vols., accompanied with very learned diſſertations: "Ancient Accounts of India and China, by two Mahometan Travellers in the 9th Century, tranſlated from the Arabic." Renaudot died in the year 1720, at the age of 74 years, greatly regretted by the literati of that age, to whom he was a communicative and moſt agreeable companion, and lamented by the poor, to whoſe relief he had dedicated a large portion of his income. Moreri.

RENAY, or Ronse, in *Geography*, a town of France, in the department of the Jemappe, with a magnificent chateau; 7 miles S. of Oudenarde.

RENCHEN, a town of the duchy of Baden; 4 miles N.N.W. of Oberkirch.—Alſo, a river of Baden, which riſes in the Ortnau, and runs into the Rhine, 10 miles N. of Oberkirch.

RENCOUNTER, formed from the French, *rencontre*, *meeting*, in the *Military Art*, the encounter of two little bodies or parties of forces.

In which ſenſe, rencounter is uſed in oppoſition to a pitched battle.

Rencounter, in ſingle combats, is uſed by way of contradiſtinction to duel.

When two perſons fall out, and fight on the ſpot, without having premeditated the combat, it is called a rencounter.

RENCOUNTRE, or Rencontre, in *Heraldry*, is applied to animals when they ſhew the head in front, with both eyes, &c. or when the face ſtands right forward, as if they came to meet the perſon before them.

Indeed, in deer, this is called *maſacre*; and, in the leopard, it is the natural ſituation. He bears ſable, in rencountre, a golden fleece.

RENDE, in *Geography*, a town of Naples, in Calabria Citra; 5 miles N.N.W. of Coſenza.

RENDER, in *Law*, a term uſed in levying a fine. A fine with render, is that by which ſomething is rendered back again by the cognizee to the cognizor.

The lawyers alſo ſay, there are certain things in a manor, which lie in *prender*, *i. e.* which may be taken by the lord, or his officers, when they pleaſe, without the tenant's leave; and others which lie in *render*, that is, muſt be rendered or anſwered by the tenant, as rents, reliefs, heriots, and other ſervices. See Prender.

Some ſervice conſiſts in ſeiſance, ſome in render.

RENDERING, in *Building*. See Pargeting.

Rendering, in *Sea Language*, is generally underſtood to be the effect of yielding or giving way, without reſiſtance, to the efforts of ſome mechanical power. It is uſually expreſſed of a complicated tackle, laniard or laſhing, when the effect of the power applied is communicated with facility to all the parts, without being interrupted in its paſſage. It is therefore uſed in contradiſtinction to jamming.

RENDEZVOUS, or Rendevous, a place appointed to meet in, at a certain day and hour.

The word is French, and is found ſo commodious, that moſt nations uſe it in its purity, for want of a word of equal import in their reſpective languages.

Thus, in a military ſenſe, the rendezvous is the place appointed by the general, where all the troops that compoſe the army are to meet at the appointed time, in caſe of an alarm; and the regiments have their particular rendezvous, called their quarters of aſſembly.

In a naval ſenſe, it denotes the port or place of deſtination, where the ſeveral ſhips of a fleet, or ſquadron, are appointed to rejoin the whole, in caſe of a ſeparation, occaſioned by tempeſtuous weather, or other unforeſeen accident.

Rendezvous *Bay*, in *Geography*, a bay on the S. coaſt of Antigua, W. of Falmouth harbour.

Rendezvous, *Iſland of*, an iſland, or rock, in the ſouthern Indian ocean, diſcovered in 1773 by M. de Kerguelen, near the N. coaſt of Kerguelen's land, and called by captain Cook "Bligh's Night-cap."

Rendezvous *Key*, a ſmall iſland in the bay of Honduras, near the coaſt of Mexico. N. lat. 16° 59'. W. long. 88° 40'.

RENDS, in a *Ship*, are the ſame as the ſeams between her planks.

RENDSBORG, in *Geography*, a town of Germany, in the duchy of Holſtein, ſeated on a canal which communicates with the Baltic, on the borders of Sleſwick, ſuppoſed to be one of the ſtrongeſt towns in the Daniſh dominions, and generally well garriſoned. The number of inhabitants is about 3600; 15 miles W. of Kiel. N. lat. 54° 22'. E. 9° 52'.

RENE', a town of France, in the department of the Sarthe; 15 miles N. of Le Mans.

RENEALMIA, in *Botany*, a new genus of Mr. Brown's, has lately received that name from him, in juſt commemoration of Paul Renealmus, or Renaulme, a phyſician at Blois, who publiſhed, in 1611, a thin quarto volume at Paris, entitled *Specimen Hiſtoriæ Plantarum*, with expreſſive, but ſtiff, and not neatly finiſhed, engravings in copper, in which each plant is diſtinguiſhed by an appropriate Greek name, moſtly of the author's invention. Mr. Brown obſerves, that this author was the firſt who paid attention to the differences in the number, ſituation, and proportion of the ſtamens. Linnæus, in his own copy of the work, has expreſſed a well-founded ſurprize, at its being never quoted by the Bauhins. Plumier was the author of the firſt *Renealmia*, now ſunk in the Linnæan *Tillandſia*. Linnæus, or his ſon, dedicated a monandrous genus, in the Supplementum Plantarum, to the memory of this meritorious botaniſt; but it proved not diſtinct from a more generally-received genus, of the ſame date, *Alpinia*. We wiſh the preſent *Renealmia* may be found ſufficiently different from *Siſyrinchium*, to which its ſpecies were originally referred by its learned author.—Brown Prodr. Nov. Holl. v. 1. addend. (Siſyrinchium; ibid. 304.)—Claſs and order, *Monadelphia Triandria*. Nat. Ord. *Enſatæ*, Linn. *Irideæ*, Juſſ. Brown.

Eſſ. Ch. Calyx none. Petals ſix, regular; three inner ones largeſt, contracted at the baſe. Style one. Stigmas three, thread-ſhaped, involute, acute. Capſule inferior, obovate, of three cells. Seeds angular.

The ſpecies are herbaceous, ſmooth, inhabitants of woods. *Roots* fibrous, ſometimes tuberous. *Leaves* graſſy, lax, ribbed. *Stem* roundiſh, ſometimes divided. *Flowers* in alternate umbellate bunches, with ſhort permanent ſheaths. *Corolla* regular, white, ſpreading, ſoon falling off; the outer petals generally greeniſh at the back; the inner often furniſhed with claws. *Filaments* either combined below, or diſtinct; their upper part ſpreading. *Capſule* membranous. *Seeds* in two rows, black.

1. R. *paniculata*. Panicled Renealmia. Brown n. 1.—Stem panicled. Leaves ribbed; roughiſh at the edge. Outer

petals

petals linear-lanceolate; inner scarcely twice as large, obovate-oblong. Filaments united half way up.—Gathered by Mr. Brown, near Port Jackson, New South Wales. The *leaves* are all from ten to eighteen inches long, and for the most part rough-edged.

2. R. *grandiflora.* Large-flowered Renealmia. Brown, under the former.—Stem panicled. Leaves ribbed; roughish at the edge. Inner petals four times as large as the outer. Filaments united half way up.—Gathered by the Rt. Hon. sir Joseph Banks, in New Zealand. Akin to the former, but differing in the proportion of its inner *petals*, which are four or five times the size of the outer.

3. R. *pulchella.* Elegant Small Renealmia. Brown n. 2. —Stem nearly simple. Leaves with smooth edges. Outer petals oval-oblong; inner obovate, with short claws. Filaments distinct.—Gathered by Mr. Brown near Port Jackson. The *leaves* are only three or four inches long.

RENE'E DE FRANCE, in *Biography*, duchess of Ferrara, born at Blois in 1510, was daughter of Lewis XII. and Anne of Britanny. She was affianced, when very young, to Charles of Austria, afterwards emperor, and some years after was fought in marriage by Henry VIII. of England, but neither of these matches took place, and Francis I. gave her to Hercules II. of Este, duke of Ferrara. This princess is celebrated for her talents: she had a great capacity, and an insatiable thirst for knowledge, and her studies were not limited to history, the languages, and mathematics, but embraced various other topics, especially astrology and theology. The religious controversies of the time greatly interested her, and she became zealously attached to the tenets of the reformers; her court at Ferrara became the refuge of all who were suspected of heresy; and her conduct gave so much offence to the court of France, that Henry II. sent a doctor to the duke with the following instructions: "If the duchess persist in her errors, she must be separated from all conversation: her children must be taken from her, and all her domestics who are suspected of heresy, and who are to be prosecuted; with regard to the princess herself, the king refers to the prudence of her husband to proceed against her as he shall judge proper, avoiding, nevertheless, what might occasion too much scandal." After the death of the duke, in the year 1559, this princess returned to France, and resided at her castle of Montargis. In the religious wars the duke of Guise summoned her to deliver up some partizans who had taken shelter with her, she replied, "I will never deliver up those who look to me for protection; and if you attack the castle, I will be the first to appear in the breach, to see if you will have the audacity to kill a king's daughter." She was, however, at length obliged, much against her will, to send away 460 persons, to whom she had afforded an asylum. She parted with them in tears, after providing for the expences of their journey. At the massacre of St. Bartholomew she was the means of saving the lives of a great number of Protestants. Her four children were taken successively from her, and brought into France, to be educated in the principles of the Catholic church. She died at Montargis, in the year 1575. Moreri.

RENEGADO REEF, in *Geography*, a rocky shoal in the bay of Honduras, near the coast of Mexico. N. lat. 16° 16′. W. long. 88° 50′.

RENEGATE, RENEGADO, a person who has apostatized, or renounced the Christian faith, to embrace some other religion, particularly Mahometanism.

They are the renegadoes who prove the most barbarous to the Christians when they fall into their hands. The renegate is thus called, *quasi re-negat Christum.*—Hoveden mentions this in the year 1192, under the name of *renier*, from the French, *renier, to deny again.*

RENDLE, in *Geography*, a river of France, which runs into the Seine near Rouen.

RENDLING CURD, in *Rural Economy*, a term used provincially to signify the broken curd in cheese-making. See CHEESE and DAIRYING.

RENES, in *Anatomy*, the Latin name for the kidnies. See KIDNEY.

RENES *Succenturiati*, the two small bodies, of which one is placed above each kidney. The literal translation of the expression, *reserve kidnies*, seems to indicate a notion, entirely unwarranted by our knowledge of their organisation and functions, that they might supply the place of the kidnies if they failed in their office. These bodies are also called capsulæ renales or atrabilariæ, and glandulæ suprarenales. They are described in the article KIDNEY.

RENESBONA, in *Geography*, a river of America, which runs into lake Erie, N. lat. 41° 47′. W. long. 81° 55′.

RENETTE, in the *Manege*, is an instrument of polished steel, with which they sound a prick in a horse's foot.

RENEWING *of Leases and Lives.* See REVERSION, ANNUITY, POLITICAL *Arithmetic*, &c.

RENFORCER, Fr., in *Music*, to reinforce, to pass from soft to loud, from loud to very loud, not all at once, but by degrees, swelling and augmenting the sound, whether a single note sustained, or a series of notes, till the order to reinforce the note or passage is fulfilled, and then return to the common degree of force.

RENFREW, in *Geography*, a royal borough-town in the county of Renfrew, Scotland, is situated near the south bank of the river Clyde, at the distance of six miles from Glasgow, and 49 miles W. by S. from Edinburgh. Though much inferior in magnitude and population to Paisley, it is the head-town, or capital of the county. This distinction it derives from its superior claims to antiquity, and from the circumstance of its being incorporated under a royal charter, originally granted by king Robert II., who had a palace in the immediate vicinity. In virtue of that deed it is governed by a provost, two baillies, and sixteen counsellors. In former times it sent one representative to the parliament of Scotland, and is now a contributary royal borough with Rutherglen in returning a member to the British legislature. About 200 years ago the Clyde passed close to the town, but the river afterwards deserted its ancient course, which has been converted into a canal communicating with its present channel. By this canal vessels of 200 tons burthen are enabled to reach the town in spring tides; but notwithstanding the advantage of that conveyance, the trade of Renfrew is very inconsiderable; owing, as Mr. Forsyth justly remarks, "to the pernicious effects of borough politics, in withdrawing men from industrious habits and pursuits." A small manufacture of thread, and some soap and candle works, on a confined scale, constitute the chief support of the town; but many of the lower orders are likewise employed in weaving for the manufacturers of Paisley and Glasgow. With respect to buildings, Renfrew consists chiefly of one principal street, about half a mile in length, with several lanes diverging from it. The houses are wholly constructed of stone, but are extremely irregular as to size, form, and position. The public buildings are the church, which is parochial, the town-hall, and a grammar-school. The last is under the patronage of the town-council, and is at present conducted with much ability. There is no regular market held here, but provisions of all kinds may always be obtained at a reasonable price. The fairs take place on the third Tuefday in May and July, the 29th of September, and the firft Friday in December. A general poft-office is eftablifhed at Renfrew. The revenue of the corporation exceeds 500*l.* *per annum*, arifing from the rents of lands, cuftoms, a falmon fifhery on the Clyde, and the profits of a public ferry over that river. This ferry is perhaps the object moft worthy of notice of any connected with the town. There is a ferry-houfe on each fide of the river, the property of the corporation; and a ferry-boat conftructed in fo convenient a manner, that a carriage, with a pair of horfes harneffed, can be ferried over and delivered by one man in five minutes. This is accomplifhed by fixing, on both banks of the river, a rope which runs upon rollers at each end of the boat, and being pulled by the boatman puts it in motion. Renfrew, as the fhire town, is the place where all county meetings are affembled, and where the county quarter feffions of the peace are held.

Renfrew parifh extends between three and four miles in every direction. The whole is level, inclofed, and in a high ftate of cultivation. The foil is a rich loam, and the climate is peculiarly healthy, though fubject to occafional heavy rains. The burgh lands confift of about a hundred acres. This parifh is interfected by the great road between Glafgow and Greenock. Ecclefiaftically confidered, it is within the prefbytery of Paifley, and the fynod of Glafgow and Ayr. According to the parliamentary returns of 1811, the number of its houfes is eftimated at 344, and its inhabitants amount to 2305. Beauties of Scotland, 8vo. vol. iii. Carlifle's Topographical Dictionary of Scotland, 4to. 1813.

RENFREWSHIRE, a county in the fouth-weftern divifion of the kingdom of Scotland, is bounded on the eaft by Lanarkfhire, on the weft, north, and north-eaft by the river Clyde, and on the fouth-weft by the hills of Ayrfhire. This county is of fmall extent, and of irregular fhape; and contains, according to the parliamentary returns of 1811, 8409 houfes, and a population of 92,596 perfons. In general, and efpecially along the northern parts of it, the furface of the ground is level; but there are neverthelefs feveral ridges of hills within its boundaries, fome of which, upon the borders of Ayrfhire, are of confiderable elevation. The hills of Balagich and of Dunware rife to the height of 1000 feet above the level of the fea; and the ifolated hill, called the Craig of Neilfton, to 820. This laft is covered with fine grafs to its very fummit. Thofe adjoining to Ayrfhire, however, are bleak and barren, but command very fine views. On the fouth and weft fides, the fertile vale of Cunningham, which feems at a diftance to be wholly covered with wood, ftretches itfelf to the fhore of the Clyde; while on the north and north-eaft are beheld the level parts of Renfrew and the city of Glafgow, with the lofty Ben-Lomond towering above the clouds, in the back ground.

The rivers and lakes of this county are not of very confiderable confequence in relation to themfelves, but by the induftry of the inhabitants on their banks, they have been rendered of great importance and utility to fociety. Unlike the romantic waters of Ayrfhire, adorned with wood and exciting intereft by the veftiges of ancient magnificence which they every where difplay, the ftreams of this diftrict are made fubfervient to the purpofes of human induftry. If they defcend from a height, it is not to add to the charms of the furrounding fcenery, but to give motion to extenfive machinery, inclofed within immenfe piles of building, where hundreds of mortals toil in the fervice of luxury, or form the materials which are to furnifh clothing to diftant nations. Here, if a ftream fpreads abroad its waters, it is not to embellifh a park, but to afford convenience to a bleach-field, or to ferve a refervoir for the mills in cafe of drought. In proportion as Glafgow is approached, every thing affumes an afpect of activity, of enterprife, of arts, and of induftry. The principal ftreams are the White-Cart, the Black-Cart, and the Grif, which fall into the Clyde below Inchinnan bridge. The White-Cart, which generally receives, by way of eminence, the Cart, runs in a direction from fouth-eaft to north-weft, nearly parallel with the Clyde. It takes its rife in the moors of Eaft Kilbride, Lanarkfhire, and is particularly celebrated in ancient record for its fine large pearls. Thefe, however, have long difappeared; but the river is become a fource of more certain and beneficial wealth by its utility to the manufacturing interefts of the county. Above Paifley, which ftands upon its banks, it winds its way through a variety of fmall hills capable of cultivation to their fummits; fometimes difappearing altogether, and again fpreading its waters abroad into the plain. Below the town it is navigable for fmall veffels, and is thus beneficial to commerce and trade by facilitating the conveyance of goods. The Black-Cart rifes out of Caftle-Semple loch, in the parifh of Lochwinnoch. From that beautiful lake it defcends northward, and receives in its courfe the waters of the Grif. This laft ftream has its fource in the elevated territory above Largs, which looks down upon the angle formed by the frith of Clyde. After its union with the Black-Cart, thefe conjoined rivers flow into the White-Cart at Inchinnan bridge. The lakes in the county, befides that of Caftle-Semple above mentioned, are Queenfide loch, in Lochwinnoch parifh, two lochs in Neilfton parifh, and various other fmaller ones, all of them appropriated to ufeful purpofes.

The mineralogy of this county, though not fo important as that of fome others in Scotland, is neverthelefs deferving of attention. In the parifhes of Eaglefham and Kilbarchan, the mineral called the ofmund ftone is frequently found. This remarkable ftone is of various colours, and when newly quarried, is fo foft that it may be cut with a chiffel; but afterwards becomes much harder. It breaks in all directions with unequal and harfh furfaces, readily abforbs water, and if recently heated, the abforption is attended with a hiffing noife. Acids do not affect it, nor is it rent or melted by a ftrong heat. Hence it is much ufed for paving ovens, furnaces, &c. When burnt, it affumes a darkifh colour, and lofes three *per cent.* of its weight, but afterwards regains it by abforption. Some of it is confiderably porous, and almoft femivitrified, in which cafe, when ftruck, it emits a clear and ftrong found. It is found in large maffes in the form of rocks, having the intervening fpaces filled with filiceous or calcareous fpar, and occafionally with zeolite, fteatites, and barytes. This laft mentioned fubftance is found in abundance at Balagich hill in the parifh of Eaglefham, where are likewife two very noted mineral fprings. But the chief field of minerals in Renfrewfhire is that in the vicinity of Paifley, which extends on the one fide into the parifh of Kilbarchan, and on the other towards Glafgow. That part of it which is moft fingular is the coal at Quarreltown, which is undoubtedly one of the moft extraordinary maffes of that mineral hitherto difcovered in the Britifh dominions. Its thicknefs, meafured at right angles, is fifty feet; and it confifts of five layers or ftrata in contact with each other. In confequence of its enormous depth, it is wrought in different floors, in the mode practifed in great open quarries. It is difficult to form a juft conception of the manner in which this fingular mafs of coal lies. In a field of fifteen acres, it is found to dip in various directions. At leaft, conceiving a nearly circular area of thefe contents, the coal, from the north, the eaft, and fouth quarters of that circle, dips pretty uniformly towards the centre. This,

 however,

however, is in fome meafure interrupted by feveral hitches, at one of which the mafs of coal is fuddenly thrown up about fifty feet, at another above thirty. Thefe hitches interrupt not only the direction, but the degree of the dip. On one fide of the northern hitch, it is about one foot in three; on the other fide, only one in fix. Some years ago, this bed of coal having taken fire, the pillars gave way and the ground funk, leaving the furface in a very rugged ftate. The difficulties thus produced, however, have been furmounted, and this mineral treafure reftored to all its utility. The other coal-mines in the county of Renfrew, are thofe of Hawkfhead, Cathcart, and Kilbarchan. The firft has been wrought above 200 years. In the fame neighbourhood, lime is quarried in great quantities, alfo in Cathcart parifh. Iron-ftone accompanies all the coal ftrata, but is more particularly abundant along the fhores of the Clyde.

On the agriculture of Renfrewfhire, it will be unneceffary to offer many remarks. Almoft every portion of the county is inclofed and cultivated, but grafs lands are far more predominant than arable fields. This arifes from the great demand which exifts for the products of the dairy, the garden, and the fold, in confequence of the vicinity of trading and manufacturing towns, and the vaft importation of grain which takes place from other parts of the country, or from abroad. Here the farmers are more fenfible than to object to a free commerce in that article; becaufe they do not envy the inhabitants of lefs populous diftricts, who find no better employment for their lands than that of fcourging them by endlefs crops of grain. One would imagine that the practice in this diftrict alone ought to decide the principle of the corn laws. Here, free importation, fo far from injuring the farmer, augments the value of the foil in every refpect, fimply by increafing the ratio of population.

The lands here differ according to their vicinity to the Clyde, or in the lower part of the county, according to their proximity to the waters of the Cart. In the parifhes of Eaft-Wood and the abbey of Paifley, the lands are beautifully interfperfed with fmall rifing hills, although the foil is generally of a thin clay. Here the farmers keep one half of their grounds in grafs, which they confider as the moft important crop. In the upper diftrict of the county, which comprehends the parifhes of Mearns, Eaglefham, Neilfton, Lochwinnoch, Kilbarchan, Erfkine, and Kilmalcolm, the lands are peculiarly adapted for pafturing fheep, but none of them are fo ftocked, excepting fome inclofures about gentlemen's feats, and a few parks in Neilfton parifh. The parifh of Mearns is perhaps unequalled in Scotland for numerous fmall hills. The farmers here make large quantities of butter. The cows are fmall, of a brown and white colour, and are chiefly of the Ayrfhire breed. Twelve of them afford, during the fummer months, about fixty Englifh gallons of milk daily. Towards the northern part of the county, in Kilmalcolm parifh, the enclofures are generally formed of ftones piled up to the height of four feet. The rotation of crops is three fucceffive crops of oats, and fix years of pafturage. Farm fervants are ufually unmarried, and live in the farmers' houfes. The horfes are of the beft kind, and draw, in a fingle horfe cart, from 17 cwt. to a ton. Farms throughout the whole county are on a fmall fcale; few of them exceed feventy acres.

Renfrewfhire contains one borough-town, Renfrew, and three large manufacturing and commercial towns; *viz.* Paifley, Greenock, and Port-Glafgow, all of which are noticed under their refpective names. Here are likewife feveral populous and thriving villages, fuch as Pollockfhaws, Bridge of Johnfton, and Lochwinnoch, which are chiefly inhabited by weavers, who derive employment from the manufactories of Glafgow and Paifley. The principal manufactured products are thread, filk-gauze, and different kinds of cotton goods.

Various remains of antiquity are ftill vifible in this county. At Paifley was a celebrated abbey for monks of the order of Clugni, the ruins of which are much admired. Here is alfo an old chapel, in the early pointed ftyle, which is noted as the burial place of Margery Bruce, and feveral of the earls of Abercorn. In the parifh of Kilbarchan, near Caftle-Semple, is one of thofe monftrous maffes of whinftone, believed to be a druidical altar. It is twelve feet in height, and fixty-feven feet in circumference; and is known by the name of Clochodrigftone, a corruption of the Gaelic, Cloch-a-Drugh, the Druid's ftone. It is compofed of the fame fort of whinftone of which the neighbouring hills are formed, and has probably been hewn from an elevated rock to the eaftward, on which is a farm-houfe, called alfo Clochodrig; but by what mechanifm it was conveyed cannot, in the prefent application of the mechanical arts, be eafily determined. It refts upon a narrow bafe; but the lower part of it has been covered with ftones gathered from the land. At fome diftance are feveral large grey ftones, fuppofed to have been part of a facred circle furrounding the altar. The parifh of Cathcart is noted for being the fcene of the battle of Langfide, the laft contefted by the unfortunate queen Mary, to regain her authority. The place where the action was fought is an eminence rifing rapidly on the north and weft fides, and defcending very gradually on the fouth and weft fides. On the fummit is an elliptical intrenchment, commonly called queen Mary's camp; but which is undoubtedly of much higher antiquity, and probably of Roman origin. On an hill, oppofite to Langfide, is the old caftle of Cathcart, near which queen Mary ftood during the battle, and witneffed the difcomfiture of her friends, and the annihilation of her hopes. On the other fide of this range of hills is another ancient caftle, now in ruins, which belonged to the anceftors of the great reformer Knox; and at a fhort diftance from it, on an elevated rock, may be feen one of thofe green artificial hills, ufually called moats. It is of a fquare form, the fides facing the four cardinal points; the weftward refts on the precipitous edge of the fteep rock; and the remaining fides are defended by a deep trench, cut out of the folid ftone. Each fide of this mount meafures fixty feet in length at the bafe, and nineteen at the fummit; and is twenty-one feet high. The top appears to have been a hollow fquare, furrounded by a parapet, with an entrance on the eaftern fide. No fewer than five other artificial mounts can be feen from the one defcribed; alfo a Roman encampment near Paifley, diftant about five miles. On the top of Barhill are the remains of a rude encampment, which occupies the fummit of a precipice, formed of a perpendicular rock of a bafaltic appearance, which defends it on the north; and on the fouth it has a parapet of loofe ftones. The tradition in the neighbourhood is, that it was an encampment of the celebrated fir William Wallace. The pinnacle of rock is fhewn where they fay Wallace fat while he enticed the Englifh forces into a bog at the bottom of the rock, where they were all deftroyed; but no hiftorian confirms this ftatement. In an ifland of Caftle-Semple loch is ftill to be feen the Pail or Peel, an old caftle, to which the lairds of Semple were accuftomed to retreat in times of unufual danger. In the lake, canoes hollowed out of fingle trees, like thofe of the Indians, have been occafionally difcovered. Lower down the country the ruins of the caftle of Newark chiefly claim attention. It ftands on the eaftern point of the bay, on which the town and harbour of Port-Glafgow is fituated.

fituated. When entire it confifted of a fquare court, with a tower at one angle, which is by far more ancient than any other portion of the building. When, or by whom it was erected, is unknown: this caftle was long the property of the Dennieftouns of that ilk, and afterwards came into the poffeffion of the family of Maxwell. In this county is a variety of objects bearing the name of the renowned and patriotic Wallace, who was a native of the village of Elderflie, in the neighbourhood of the town of Paifley. See Wallace.

The only other objects of antiquarian intereft we fhall mention, are four communion cups, ftill preferved in Kilmalcolm parifh, and which were ufed by John Knox in adminiftering the facrament of our Lord's fupper. They appear to have been originally candlefticks; and it was perhaps only from the neceffity of the times that they were converted to this pious purpofe. They are of the pureft filver; and, whether from the affociation of ideas, or their actual fafhion, have a very antique and venerable appearance. Beauties of Scotland, vol. iii. 8vo. 1806.

RENGAH, a town of Sweden, in Weft Bothnia; 30 miles N.N.W. of Umea.

RENGO, a town of Sweden, in the province of Tavaftland; 8 miles S.S.W. of Tavafthus.

RENI, Guido, in *Biography*, the principal painter of the Caracci fchool, was born at Bologna in 1574. At an early age he became the difciple of Denis Calvart, a Fleming of great reputation, but afterwards ftudied under the Caracci, preferring the ftyle of Ludovico to that of Annibal, becaufe there appeared more of grandeur and of grace in his compofitions than in thofe of the others.

When he left the Caracci, he went to Rome; and with a mind intent upon forming a ftyle of art for himfelf, ftudied the works of Raphael, with which he feemed enraptured; but the vigour and force with which the recent works of Caravaggio were conducted attracted him, and for a while he attempted to follow it. Happily he was diverted from it by an obfervation of Annibal Caracci; *viz.* that the beft mode of rivalling the renown of Caravaggio might perhaps arife from a different mode of art, by contrafting his confined and lamp-like effects with a broader and more ample light; and for his vulgar forms, and obfcure outline, fubftituting clearnefs in the parts and forms, built upon the pure models of antiquity. This remark, made in fpleen by Caracci, operated powerfully on the mind of his fkilful pupil, and induced him to try its truth. He immediately devoted himfelf to the ftudy of what was graceful and agreeable in form, colour, and effect; and his fuccefs is teftified by numberlefs beautiful productions, of which we poffefs many in England; and France is ftill more rich in them.

His compofition is not, however, fo free from affectation as the nature of the fubjects he chofe demanded; the very attempt to make them graceful, too frequently militated againft its object, and he fubftituted the grace of the theatre for that of nature. In his female heads and proportions, his model was the antique: and the character and features of the daughter of Niobe is difcernible in moft of them. He dreffed them with becoming elegance, and executed the different parts with great freedom and truth of pencil; not unfrequently, however, in a tone of colour too light, or too leaden for flefh; with a greenifh hue, which rather characterifes the hand of death, or the coldnefs of marble, than the glowing warmth of life, and the flexile foftnefs of nature.

His difpofition of draperies was elegant; judicioufly applied to the filling up of voids in the grouping of limbs, or figures, and was wrought with the greateft freedom; yet finifhed with almoft minute attention to the foldings. Thefe he arranged in a grand ftyle, but they not unfrequently exhibit the ftudy which he beftowed upon them; and appear to arife rather from the neceffities of art, than the actions of the figures. The execution of his pictures is of the moft free and agreeable kind; manifefting a perfect underftanding of nature; the touch being light, full, and delicate; and though they are finifhed very highly, yet there remains no appearance of labour. In expreffion, he fometimes attained the greateft perfection; as in the head of our Saviour in the Louvre, and of which the prefident Weft has a very fine duplicate: but, in general, it was rather the grace and artifice of the theatre which guided him; and his figures appear to act more than to feel. Such was the refpect paid to his abilities, that he was crowned with honour and riches; but it is lamentable to add, that one vice, in which he indulged after he had paffed the meridian of life, *viz.* gaming, robbed him of both, and reduced him to poverty and difgrace; from which he was not able to free himfelf during the remainder of his life, which continued till he had attained the age of 67.

In the gallery of the Louvre there are between 30 and 40 of the works of Guido, large and fmall, and in his various manners; and as he there comes in immediate competition with his mafters, connoiffeurs have an excellent opportunity of judging of his comparative merit. We have alfo a great many of his cafel pictures in England, but they are fcattered about in various collections.

Reni, in *Geography*, a town of European Turkey, in Beffarabia, on the Danube; 40 miles W. of Ifmail. N. lat. 45° 23′. E. long. 28° 44′.

RENIFORME Folium, in *Botany*, a kidney-fhaped leaf. See Leaf.

RENNES, a city of France, and chief city of the department of the Ille and Vilaine; and, before the revolution, the fee of a bifhop, and capital of Bretagne; fituated on the Vilaine, by which it is divided into two parts. It is large and populous, containing eight parifh churches, befides the cathedral and feveral convents. The four parts which it comprehends are denominated the north-eaft, fouth-eaft, fouth-weft, and north-weft The firft contains 5950 inhabitants, and its canton 13,147, on a territory of $142\frac{1}{2}$ kiliometres, in 7 communes; the fecond contains 5253 inhabitants, and its canton 12,064, on a territory of $97\frac{1}{2}$ kiliometres, in 4 communes; the third contains 3081 inhabitants, and its canton 12,254, on a territory of $142\frac{1}{2}$ kiliometres, in 9 communes; and the fourth part contains 11,620 inhabitants, and its canton 14,332, on a territory of $37\frac{1}{2}$ kiliometres, in 3 communes. N. lat. 48° 7′. W. long. 1° 36′.

RENNET,

RENNET, in *Rural Economy*, a term applied to the coagulum for making cheeſe. It is prepared from the bag, maw, or ſtomach, of the young calf, by a ſort of ſalt pickle. It is of vaſt advantage in the art of cheeſe-making to have good ſweet rennet, the particular mode of managing which may be ſeen under the heads CHEESE, DAIRY, and DAIRYING.

The preparation is formed in different modes, in different cheeſe diſtricts, in the different parts of the kingdom; but moſtly either in the manner of a ſolution, or that of a dry ſkin. As there is, however, much variation in the quality or ſtrength of the different ſkins, it is probably the beſt method to reduce them into the ſtate of a ſolution; as, by that means, the neceſſary quantity, in every caſe, may be the beſt aſcertained.

In ſome places, it is found the moſt certain practice to prepare the whole of the dried maw ſkins, which are required for a ſeaſon, at one time, by pickling and ſteeping them in different ſeparate quantities of pure ſpring water and ſalt, in an open veſſel, or veſſels, mixing the different infuſions together, and then paſſing them through a fine linen ſieve, afterwards adding rather more ſalt to the whole than can be retained in the ſtate of ſolution, as ſhewn by the appearance of ſome at the bottom of the veſſel. The extraneous ſcummy matter, that comes to the ſurface, is continually to be removed as it riſes, and freſh portions of ſalt occaſionally ſupplied, as they may be wanted. In this ſtate it is ready for uſe, about four ounces being ſufficient for a large cheeſe.

In other parts, the maw ſkins are ſimply well ſalted, and ſteeped in ſalt pickle for ſome length of time; then well dried, by being ſpread out by means of ſmall pieces of ſticks; in which ſtate they are made uſe of, by cutting pieces from the top and bottom parts of them, about the ſize of a half-crown for a middling-ſized cheeſe, as thoſe parts are in general the ſtrongeſt.

And the following method of preparing rennet is practiſed in the northern parts of the iſland, and deſcribed as the moſt approved method in the Report on Agriculture for Argyleſhire. Take the maw ſkin of a calf, which has fed entirely upon milk: after it is cold, waſh it gently in water, fill it nearly with ſalt, and place it on a layer of ſalt in the bottom of an earthen mug. One or two more, with ſalt between, and a good deal above them, may be put in the ſame mug, and kept in a cool place, with a ſlate on the top, for ſix or eight months, or till cheeſe-making time next year. The ſkins are then taken out, and the brine allowed to drain from them; after which they are diſtended on ſmall hoops or ſplinters put croſs-wiſe within them, till they dry. Put the ſkins then in an open veſſel, with three pints of pure ſpring water for each ſkin. Let them ſtand twenty-four hours; after which take them out, and infuſe them other twenty-four hours in other water, but not more than a third of the former quantity. Mix theſe two infuſions together, paſs them through a fine linen ſieve, and give them ſalt till the water is more than ſaturated, and ſome remain undiſſolved at the bottom. Rather leſs than a gill will ſerve for thirty-eight pounds of cheeſe. It is remarked, that, inſtead of two infuſions, ſome uſe only one, giving four Engliſh pints to the ſkin, and direct the water to be firſt boiled, and mixed with ſalt into brine that will ſwim an egg, and then to let the heat go off till it is lukewarm, before the ſkin is put in twenty-four hours to ſteep.

It was formerly the practice to mix different kinds of aromatic herbs with the rennet; but the cuſtom is much laid aſide at preſent. The manner of doing it is this: when the maw ſkin is well prepared, two quarts of ſoft pure water ſhould be mixed with ſalt, in which ſhould be put ſweet briar, roſe-leaves, and flowers, cinnamon, mace, cloves, and, in ſhort, almoſt every ſort of ſpice and aromatic that can be procured. Boil them gently till the liquor is reduced to three pints, taking care it be not ſmoked. Strain it clear from the ſkins, and, when milk-warm, pour it into the maw; a lemon may then be ſliced into it, and remain a day or two, after which it ſhould be ſtrained, and put in a bottle well corked, and it will keep good for a year or more. A ſmall quantity will turn the milk, and give the cheeſe a pleaſing flavour.

RENNO, in *Geography*, a town of the iſland of Corſica; 3 miles N.E. of Vico.

RENO, a river of Italy, which riſes a little to the N. of Piſtoia, and runs into the Po, 4 miles above Ferrara.

RENO, a department of Italy, ſo named from the above-mentioned river. It conſiſts of part of the Bologneſe, and contains 199,300 inhabitants, who elect 15 deputies. The capital is Bologna.

RENOGRUND, a ſmall iſland on the E. ſide of the gulf of Bothnia. N. lat. 63° 59′. E. long. 23° 3′.

RENOVATOR, in *Horology*, is a watch that has the property of *renewing* the power of its main-ſpring, or of winding itſelf up, by periodic jerks that it receives from the human body in motion. Recordon of Charing-Croſs, London, took out a patent for this contrivance ſome years ago, which is more ingenious than uſeful; for, while it profeſſes to keep the watch going, without the uſual winding up, ſo long as the watch is worn in the pocket, it foregoes the more uſeful property of the fuſee, and renders the maintaining power very unequal at different times of the day. And ſhould the watch remain ſuſpended, or laid down in a ſtate of reſt, for more than 24 hours, it will ceaſe to perform; ſo that inſtead of being a watch that will go without winding, it requires to be wound many hundred times in the day, by ſmall ſucceſſive quantities, before it will continue to perform throughout the night. We have been favoured by the inventor with a copy of ſo much of the ſpecification as will ſuffice to give our readers an idea of the mechaniſm, and of its mode of action; both which we have examined, and found correſponding with the ſpecification. Others have varied the conſtruction; but the original, we conceive, will be deemed ſufficient for us to particularize, which we will do by a reference to *figs.* 1, 2, and 3, in *Plate* XLIII. of *Horology*, which are copied from the inventor's drawing.

Exact Copy of the Specification, N° 1.—"Letter H repreſents a weight of ſilver, or other metal, which is in equilibrium in the poſition it is viewed, being ſuſtained ſo by a ſpiral ſpring fixed to its arbor, as deſcribed by *fig.* 3. In wearing the watch, or by any external motion that lifts the watch up, it loſes its ſtate of reſt; and by its vis-inertiæ (matter) overcoming the ſtrength of the ſpring, it yields to the laws of gravity, and falls upon the lower ſpring, marked *e e*. When the watch, by the motion of the body, deſcends, the ſpring *e e*, and the aforeſaid ſpiral ſpring, are left at liberty to exert themſelves, and return the weight upwards, till it touches the other ſpring *e e*; and thus, by the motion of the body, is this weight alternately thrown up and down, which turning the ratchet-wheel, marked C in *fig.* 2, which is fixed on the arbor of the weight juſt below the ſpiral ſpring, gathers a few teeth every motion in the wheel P, and being prevented from returning by the click M, carries forward the wheel with a pinion of 10, marked E, which turns the wheel B; which having a pinion of 12 at G, takes into and turns a wheel under the barrel A, which is fixed on the barrel arbor, and by that means is the ſpring wound up.

The upper part of the barrel arbor, marked *b*, has a tooth, which gains a tooth in the wheel, *a*, every revolution; and that brings the pin *c* nearer to the centre, which, when it arrives in a certain position, raifes the piece K (*fig.* 1.), of which the centre, B, (not feen in the figure) is conical, in order that when the faid pin *c* comes near it, it raifes it with eafe, and forces it into the holes, marked N, N, N, in the weight marked H (*fig.* 1.), which effectually ftops its motion, and prevents the ill confequence of over-winding.

L is a cock that carries the pivot of the barrel's axis.

I is a cock that carries the pivot of the wheel H.

A is the barrel which carries a wheel, that catches the pinion D, which carries the minute-hand."

The patent was obtained in July 1780; and part 2d of the fpecification contains drawings, and a plan for applying the fame principle to the fufee; but we do not underftand that it has yet been made to anfwer.

RENRITH, in *Geography*, a town of Germany, in the county of Henneberg; 3 miles S. of Schleufingen.

RENS, RENSE, or *Rees*, a town of France, in the department of the Rhine and Mofelle; near which, in the Rhine, is a remarkable monument of antiquity, called the "Königftuhl," or "Thronus regalis," confifting of a round vault, built of free-ftone, and refting upon nine ftone pillars, one of which ftands in the middle. This vault is 80 feet in circumference, furnifhed above with feven feats, agreeable to the number of electors at that town. The afcent to it is by ftairs of ftone, confifting of 28 fteps, and it has two ftrong doors. On this regal chair the electors formerly held previous confultations for fome time, concerning the election of a king and emperor; and when that election could not be performed at Francfort, it was done at this place; and here were alfo tranfacted the notification and elevation of the elected perfonage, and alfo the confultations of the electors concerning the weighty matters of the empire, as well as a folemn confirmation of their privileges on the part of the emperors. Here alfo was eftablifhed, in the year 1338, the electoral league. Maximilian I. is thought to be the laft emperor who was brought hither; 5 miles S. of Coblentz. N. lat. 50° 18'. E. long. 7° 37'.

RENSEN, a lake of Pruffia, in the palatinate of Culm; 10 miles N.N.E. of Culm.

RENSSELAER, a county of New York, bounded N. by Wafhington county, S. by Columbia, E. by part of the ftates of Maffachufetts and Vermont, and W. by Hudfon river. It contains eight townfhips, *viz.* Troy, Greenbufh, Schodack, Stephentown, Peterfburg, Hofick, Pittftown, and Schactekoke. It contains 36,309 inhabitants.

RENSSELAERVILLE, or RENSSELAERWICK, a townfhip of Albany county, New York, bounded S. by Columbia county, and W. by Hudfon river. In this townfhip, oppofite to the city of Albany, is a medicinal fpring, combining moft of the valuable properties of the celebrated waters of Saratoga.

RENT, REDITUS, in *Law*, a profit, fuch as a fum of money, or other confideration, iffuing yearly out of lands or tenements, alienated on that condition.

The word rent, or render, *reditus*, fignifies a compenfation, or return; it being in the nature of an acknowledgment given for the poffeffion of fome corporeal inheritance. Co. Litt. 144.

It is thus called from the corrupt Latin, *rendita*, for *reddita*, of *redditus;* becaufe, as Fleta tells us, *retroit, et quotannis redit.*

The original of rents is to be fought for in the conftitution of the ancient feuds, which were of a military nature, and in the hands of military perfons: however, the feudatories, being under frequent incapacities of cultivating and manuring their own lands, foon found it neceffary to commit part of them to inferior tenants, obliging them to fuch returns in fervice, corn, cattle, or money, as might enable the chief feudatories to attend their military duties without diftraction; which returns, or *reditus*, were the original of rents.

Under the pure feudal fyftem, this reditus, return, or rent, confifted, in chivalry, principally of military fervices; in villenage, of the moft flavifh offices; and in focage, it ufually confifts of money, though it may ftill confift of fervices, or of any other certain profit.

Rent is regularly due and payable upon the land from whence it iffues, if no particular place is mentioned in the refervation (Co. Litt. 201.); but, in cafe of the king, the payment muft be either to his officers at the exchequer, or to his receiver in the country. (4 Rep. 73.) And ftrictly the rent is demandable, and payable before the time of funfet of the day in which it is referved; though fome have thought it not abfolutely due till midnight. 1 Saund. 287. Prec. Chanc. 555. Salk. 578.

The ufual remedy for non-payment of rent is diftrefs; however, by the common law, diftreffes were incident to every *rent-fervice*, and by particular refervation to *rent-charges* alfo, but not to *rent-feck*, till the ftatute 4 Geo. II. c. 28. extended the fame remedy to all rents alike. Moreover, by this ftatute it is enacted, that every landlord, who hath, by his leafe, a right of re-entry in cafe of non-payment of rent, when half a year's rent is due, and no fufficient diftrefs is to be had, may ferve a declaration in ejectment on his tenant, or fix the fame upon fome notorious part of the premifes, which fhall be valid, without any formal re-entry or previous demand of rent. And a recovery in fuch ejectment fhall be final and conclufive, both in law and equity, unlefs the rent, and all cofts, be paid or tendered within fix calendar months afterwards. Other remedies are action of debt, an affife of mort d'anceftor or novel diffeifin, the writ de confuetudinibus et fervitiis, which compels a fpecific payment of the rent, the writ of ceffavit, and the writ of right fur difclaimer.

For an account of the rental of England and Wales, fee POLITICAL *Economy*.

The lawyers ordinarily reckon three forts of rents, *viz.* *rent-fervice*, *rent-charge*, and *rent-fec*.

RENT-*Service*, is where a man holds lands of his lord by fealty, and certain rent; or by fealty-fervice, and certain rent; or that which a man, making a leafe of lands to another for term of years, referveth to be yearly paid for them.

Rent-fervice is fo called, becaufe it hath fome corporal fervice incident to it, as at the leaft fealty, or the feudal oath of fidelity. (Co. Litt. 142.) For, if a tenant holds his land by fealty, and 10*s*. rent; or by the fervice of ploughing the lord's land, and 5*s*. rent: thefe pecuniary rents, being connected with perfonal fervice, are therefore called rent-fervice. And for thefe, in cafe they be behind, or in arrear, at the day appointed, the lord may diftrein of common right, without referving any fpecial power of diftrefs; provided he hath in himfelf the reverfion, or future eftate of the lands and tenements, after the leafe or particular eftate of the leffee or grantor is expired. Litt. § 215.

RENT-*Charge*, is where a man makes over his eftate to another by deed indented, either in fee, or fee-tail, or for term of life; yet referves to himfelf, by the fame indenture, a fum of money yearly to be paid to him, with a claufe of diftrefs diſtreſs for non-payment: ſo called, becauſe, in this manner, the land is charged with diſtreſs for the payment of it. Co. Litt. 143.

Rent-*Sec*, or *Dry-Rent*, or *Barren-Rent*, is that which a man, making over his eſtate by a deed indented, reſerveth yearly to be paid to him, without any clauſe of diſtreſs mentioned in the indenture. There are alſo other ſpecies of rents, which are reducible to theſe three.

Rents *of Aſſize*, are the certain eſtabliſhed rents of the freeholders, and ancient copyholders of a manor; thus called, becauſe aſſized and certain, in oppoſition to *reditus mobiles*.

Thoſe of the freeholders are often called *chief rents*, *reditus capitales*, and both ſorts are indifferently denominated *quit rents*, becauſe by them the tenant goes quit and free of all other ſervices. When theſe payments were reſerved in ſilver or white money, they were anciently called *white* rents, or blanch-farms, *reditus albi;* in contradiſtinction to rents, reſerved in work, grain, or baſer money, which were called *reditus nigra*, or black-mail. 2 Inſt. 19.

Rent, *Fee-farm*, is a rent-charge iſſuing out of an eſtate in fee; of at leaſt one-fourth of the value of the lands at the time of its reſervation. (Co. Litt. 143.) *Rack*-rent is only a rent of the full value of the tenement, or near it. For a grant of lands, reſerving ſo conſiderable a rent, is indeed only letting lands to farm in fee-ſimple, inſtead of the uſual method for life, or years.

Theſe are the general diviſions of rent; but the difference between them (in reſpect to the remedy for recovering them) is now totally aboliſhed; and all perſons may have the like remedy by diſtreſs for rents-ſec, rents of aſſize, and chief-rents, as in caſe of rents reſerved upon leaſe. Stat. 4 Geo. II. c. 28.

Rents *Reſolute*, are reckoned among the fee-farm rents to be ſold by the ſtat. 22 Car. II., being ſuch rents or tenths as were anciently payable to the crown from the lands of abbeys and other religious houſes; which lands, upon the diſſolution of abbeys, being demiſed to others, the ſaid rents were ſtill reſerved, and made payable to the crown.

Rents, *aſſart*, *chauntry*, *chief*, *gold*, *paſchal*, *rack*, *quit*, and *white*. See the ſeveral adjectives.

Rent, in *Agriculture*, the price paid for lands as farms by the tenants of the proprietors. The rents of lands are ſo extremely various, according to the nature of the ſoil, ſituation, markets, the ſtate of the fences, buildings, and other conveniences, the eaſe of obtaining manures, and many other circumſtances, as to be almoſt incapable of having any general ſpecific prices affixed to them. They were formerly, eſpecially in the northern parts of the iſland, paid in produce and perſonal ſervices; but at preſent, according to Mr. Donaldſon, over the greateſt part of the iſland, they are paid in money, and at two periods or terms in the year. In England, Michaelmas and Lady-day are the cuſtomary terms of payment; the firſt payment commences ſix months after entry to the poſſeſſion of the farm. But that in Scotland, the ordinary terms are Martinmas and Whitſuntide, or Whitſuntide and Martinmas, the tenant being allowed twelve months' credit of the firſt half of the rent in the one caſe, and in the other eighteen. And he obſerves, that this difference in the terms of the payment of rents is material in the purchaſe of landed property, being in general nearly one year's purchaſe in favour of England. And it is farther ſtated, that it was the cuſtom of former times, in various parts of Great Britain, for the tenants to pay what was called *fore-hand* rents, that is, paying the half, and in ſome caſes, the whole year's rent immediately on entering to the farm, and before any benefit was derived from the poſſeſſion of it. This practice is, however, now generally diſuſed, although ſtill kept up in ſome parts of Staffordſhire and Perthſhire, in ſome degree. And we believe that it ſtill prevails in ſome places in Ireland. It is likewiſe added, that letting lands for a term of years at the former rent, but making the farmer pay a conſiderable ſum in ready money by way of fine, was alſo a very common cuſtom; but is now chiefly confined to the crown and church lands in England. This mode was evidently attended with bad conſequences. By draining the tenant of all, or greateſt part of his ready money, he was prevented from improving his farm. Leaſes of lands are conſidered in law as heritable property; therefore, in the event of the demiſe of the tenant, ſoon after having completed a tranſaction of this nature, his eldeſt ſon ſucceeded to the leaſe, and the widow and other children were of courſe, in many inſtances, reduced to poverty; all that was left to them being their proportion of the ſtock on this farm, and often thereby the heir was rendered incapable of keeping poſſeſſion of the farm. In a word, in nine caſes out of ten, it was robbing the tenant of the well-earned reward of his induſtry, during the exiſtence of the former leaſe, and depriving him of the means of turning his new acquiſition to the beſt account; without giving any ſolid advantage in return for it.

It is remarked alſo, that along the greateſt part of the eaſt coaſt of Scotland, which is the principal corn country in the kingdom, a conſiderable proportion of the rent of almoſt every farm is paid in grain and oatmeal. Theſe articles being leſs fluctuating in their value than money, this appears the moſt equitable mode in which the rents of corn farms can be paid. It may indeed affect the farmer's intereſt when any ſudden and unexpected riſe takes place in the price of grain; but if a judgment can be given from experience, it will be found this very ſeldom happens. On the contrary, for theſe laſt twenty years, with only two exceptions, 1783 and 1795, the price of grain, owing to the operation of the corn laws, has been extremely moderate, while every other production of a farm has been doubled in value, and in many caſes tripled. Since theſe periods, the price of this article has, however, riſen, and continued high. The public are often eſſentially benefited by ſo great a proportion of the rents being paid in this way. Many of the proprietors have granaries erected on their eſtates, where, in times of plenty, they ſtore the grain and meal which they receive from their tenants. And every perſon, who is in any degree acquainted with the agricultural exports and imports which take place between ſome diſtricts in Scotland and others, muſt, he thinks, know that the ſupplies afforded on many occaſions from theſe ſtorehouſes have been the means of preventing ſcarcity, and an unreaſonable advance in the price of theſe articles in the large manufacturing towns and other populous places. In Eaſt Lothian, according to the agricultural report of that diſtrict, it has been ſuggeſted by ſome proprietors, that one half of the rent ſhould only be paid in money, the other in kind; and aſſigned as a reaſon, that the profit or loſs ariſing from any material, as the riſe or fall in the price of grain, would, in that way, be equally divided between the landlord and tenant. This is a mode probably founded on equity and juſtice. And it is further ſtated, by the firſt writer, that in the moſt northern parts of Scotland, the rents are, to a certain extent, paid in perſonal ſervices. The tenants are bound to plough and harrow a certain portion of the landlord's farm, to reap, carry home, threſh, dreſs, and mill a certain quantity of the crop. They are alſo bound to pay poultry, eggs, butter, cheeſe, ſheep, ſwine, linen

linen yarn, fiſh, &c.; in a word, they are more the ſlaves of the landlord than their own maſters.

Theſe are ſhameful feudal practices, which the proprietors of ſuch lands ſhould remove as ſoon as poſſible, as without it their intereſts muſt ſuffer greatly from the lands remaining without improvement. Beſides, it is a ſpecies of bondage highly diſgraceful to civilized ſociety. The able author of the Agricultural Report of the county of Argyle in Scotland, thinks that all ſervices, whether paid to the maſter or to any under him, ſhould be entirely aboliſhed; and all rents formed into one ſum of money, including public burdens, ſuch as miniſters' ſtipends, ſchoolmaſters' ſalary, road money, &c. Thus, ſays he, the tenant would have always a clear view of the amount of his rent, and ſave time and trouble, and perhaps expence, by having to ſettle with one only inſtead of many. His time is precious, and ſhould never be thrown away without neceſſity.

In regard to the parliamentary and parochial taxes, they may be ſaid to be paid, the firſt writer ſays, by the tenants over the greateſt part of both kingdoms; and many leaſes contain a clauſe, he obſerves, binding the tenants to pay, not only all the taxes that are impoſed, but alſo all that may be impoſed. But, he thinks, that it appears abſurd that the proprietors, whoſe intereſt it is to attend to the increaſe or decreaſe of all ſuch taxes as more immediately concern their property, ſhould devolve the payment of thoſe taxes on their tenants. They muſt know, that whoever pays them in the firſt inſtance, to them the lands are of leſs value, in conſequence of ſuch taxes having been impoſed. They ought alſo, he thinks, to conſider that their influence might be the means of keeping the moſt extravagant of them, ſuch as the tithes and poors' rates, within more reaſonable bounds, than it is to be expected the utmoſt exertions of the tenants can be able to effect. And that, further, proprietors could aſcertain the value of their property with more minute exactneſs, were they, on the one hand, to receive from their tenants the full rents which their lands are worth, and, on the other, pay all taxes to which they are ſubjected. The intereſt of agriculture, and the eaſe and comfort of the farmers, would at the ſame time, he thinks, be eſſentially promoted, were they relieved from theſe teaſing exactions and compoſitions with which they are ſo frequently moleſted, particularly in this part of the kingdom.

And he ſuggeſts, in reſpect to the general price of renting lands, that when it is conſidered how many circumſtances operate in determining the rent of land, and how much theſe frequently vary in the ſame pariſh or lordſhip, it will be found impoſſible to form any correct idea in regard to the rents payable by the acre for the various kinds of ſoil over the whole iſland. Any conjecture that may be formed (for the ſubject admits, he ſays, no more) muſt be vague and incorrect. It is ſuppoſed, that the remarkable change that has taken place in the ſituation of the kingdom and the manners of the people, by the abolition of the feudal ſyſtem, the increaſe of commerce, manufactures, and agricultural improvements, with the immenſe additional quantity of paper-money introduced within theſe few years into circulation, have had the effect of enhancing both the value and rent of lands. While theſe flouriſh, and paper-money ſupports its nominal value, lands in property or leaſe muſt neceſſarily, he thinks, continue to advance. But that, ſhould any croſs accident interrupt the former, or depreſs the value affixed to the latter, the recent great advance in the rent of lands, in various parts of the iſland, would render ſuch calamities more univerſal in their effects, and of courſe of more ſerious conſequence to the country.

The rent of land is kept up by a great variety of local cauſes, as the particular nature of the farms, their extents, the goodneſs of the roads and markets, the convenience of canals and other ſorts of water carriage, and many other circumſtances of a ſimilar nature. In dairy and graſs diſtricts, as well as ſome others, rents are kept up by the particular modes of occupation, in many inſtances. Many little advantages are connected with the former; while the latter has not any heavy expences to contend with. Small farms are conſtantly higher rented than thoſe of the larger kind. Convenient carriage and large markets are always favourable to rents. Local convenience has invariably great influence in raiſing the rent of land. In ſhort, it has been ſuggeſted by an able writer, that every ſort of improvement in agriculture, as well as manufactures, has a tendency to advance the rent of land; and that, if, to the practical excellence of the former, improvements in the latter ſhould be added, with a more extended commerce, rents may be raiſed to an extraordinary degree. While the contrary of theſe matters is calculated to reduce the quantity of wealth, and, of courſe, to lower the rent of land; conſequently rent riſes and falls with the proſperity or declining ſtate of the agriculture, the manufactures, and the commerce of the country, the former of which is only to be preſerved by peace.

But though the rents of land have been greatly increaſed within theſe few late years, it is probable that they muſt feel the effects of the vaſt load of taxation and other charges which bear ſo hard upon agriculture at preſent.

But the aſcertaining of the rents of lands in the different diſtricts of the kingdom is a point of conſiderable importance both in a political and agricultural view, as by ſuch means the produce of them may be better and more certainly calculated.

Mr. Smith, in his valuable Agricultural Survey of Argyleſhire, ſtates, that the quality of the ſoil is there extremely different; ſo that ſuch valuations as have been lately made, differ, ſometimes on the ſame farm, from 2*s.* to 15*s.* the acre of arable ground. The paſture, too, being partly green hill, but moſtly heath, differs no leſs in its quality than the arable land. Some of it is valued below 4*d.* and ſome above 4*s.* the acre. In the neighbourhood of Campbelton, a few ſpots of arable land let from 2*l.* to 3*l.* the acre. But this price may be ſaid to be put, not altogether upon the land, but partly upon the accommodation. But what proportion the rent of a farm ſhould bear to its produce, depends ſo much on ſoil, climate, ſituation, and other circumſtances, that no general rule can, he thinks, be laid down on the ſubject. In regard to arable lands more particularly, it is a common, though perhaps not a juſt remark, that one-third of the produce ſhould go for rent, one-third for expence and management, and one-third for the farmer's profit, intereſt, &c.

But Mr. Middleton remarks, that the method practiſed by ſome gentlemen, of eſtimating the produce of land by trebling the rent, is very fallacious: three times the rent is not by any means equal to the value of the produce of the land under the beſt ſyſtem of huſbandry now in uſe; though under the old exploded courſe of fallow, wheat, oats, in the ſcanty produce of common fields, and when taxes and the expences of living were at one-half of the preſent amount, it was not very diſtant from the truth. But under the more improved courſes of huſbandry on land, at and under twenty ſhillings an acre, the produce is now, he thinks, more generally worth from five to ſeven times the rent.

In the North Riding of Yorkſhire, as ſtated in the report of that diſtrict, the average rent of farms of pretty good ſoil is from 15*s.* to 21*s.* *per* acre, in which there may be land rated at at from 5*s.* to 35*s.* *per* acre, fo that the average value of a farm will vary according to its proportion of good and bad land. Some farms of the latter kind may be let as low as 5*s.* *per* acre, and fome let cheaper at 30*s.*; fo great is the inequality of the foil, that nothing accurate on this head can be ftated. Near large towns, land for convenience in fmall parcels, and in the aggregate to no great amount, is let at 3*l.* or 4*l.* *per* acre.

But in the weftern diftrict of that county, as about Skipton and Settle, the lands were found to let as high as 40*s.* and 50*s.* the acre; while from the beft information in the corn part of the county at the fame time, 20*s.* and 30*s.* were confidered as a high rent, and in many places it was ftill much lower.

In Shropfhire, the rents of lands, where the roads are bad, and the grounds little improved, are from 8*s.* to 12*s.* the ftatute acre, and in more favourable diftricts and fituations, from 15*s.* to 20*s.* the farm together. But near towns, the price is much higher, as from 2*l.* to 6*l.* the acre.

And in Norfolk, according to Mr. Young, in the light fand diftrict, as marked in the Survey, the average price of letting is 6*s.* the acre; the various loams at 16*s.*; the better fands at 12*s.*; the rich loams 26*s.* and the marfh land clays 28*s.* In Suffolk the feveral foils are ftated to be rented as below, the whole county included, fheep-walk, wafte commons, &c. which are very large deductions from the rate of the cultivated lands:

	s.	*d.*
Strong, wet loam, *per* acre - - -	13	0
Rich loam - - - - -	14	0
Sea diftrict of fand - - -	10	0
Weftern diftrict of ditto - - -	5	0
Fens - - - - - -	2	6

But in all the diftricts, with the exception of the fen, there are tracts that are let at 20*s.* to 25*s.* and even higher, efpecially meadows.

In the county of Effex, the average rent of good landed farms may be ftated at about 20*s.* or 25*s.* the acre. They have lately increafed very much in fome places.

In Suffex, good land is rented at from 20*s.* to 30*s.* the acre, but there is a great deal let at much lower rents. Land has rifen much of late years in many parts of the country.

In the county of Oxford, the rent of land is very various. The red land lets on the average at 30*s.*, the mifcellaneous loams at 25*s.*; the ftone-brafh at 20*s.*; and the Chiltern at 16*s.* the acre. There are, however, large portions of land let at ftill lower rents in different parts.

In Chefhire, the land averages full 30*s.* the acre in rent as farms; and in Lancafhire, the rent of land is equally as high, if not higher.

In the very fouth-weftern diftrict of Cornwall, the rents of land fluctuate very greatly, as from 5*s.* to 50*s.* the acre in farms properly fo named. The circumftances affecting rents here, befides the quality of the foil, and the afpect or fituation, are the vicinity to fea fand, and to market towns. There are inftances of land letting very high in particular fituations, as at 13*l.* the acre about Penzance. And in the fame parifhes the rents of land fometimes vary from 8*l.* to 5*s.*; nay, even on the fame farm, not exceeding 150 acres, fome parts are worth 50*s.*, and others not 5*s.* the acre.

The neighbourhood of towns and large markets, as well as of extenfive manufactories, has, in all cafes, a tendency to raife the rent of land, whether as farms or otherwife, in every part of the kingdom.

In all parts of Scotland, even in the Highlands, the rife of rents has been gradual and progreffive for many years, and in fome places they have been more than doubled within thefe laft twenty-five or thirty years.

It has been ftated by Mr. Collingfworth, of Daventry, in the fourth volume of Communications to the Board of Agriculture, that in refpect to the principle of increafing rents, where liberty is given to break up old grafs or pafture lands that are under leafe, that he has known, within this five years paft, a double rent given for leave to plough up an old pafture for cropping for three years; and that confequently it appears to him that a ftatement of the expences and profits upon arable and pafture lands fhould be feverally made out, to afcertain by how much the balance of profit of the one exceeds that of the other. He therefore ftates them, upon a probable calculation, in the following manner:

Table of Expences.

By this means the rent that can be afforded to be given may be afcertained with tolerable correctnefs in many inftances of farming. See Grass *Land*.

The author of the Argylefhire Agricultural Survey, after remarking that there is very little arable land in that county but which is capable of higher cultivation, befides the great quantity of wafte ground that may be improved in almoft every farm, fays, that the land is therefore capable of being made to yield a much higher rent when better cultivated; though not a great deal of it, as is generally thought, can bear much more, in the prefent ftage of improvement, than what is laid on already, unlefs it be under a different management, which in fheep lands might be by the introduction of better woolled breeds, and in arable lands by adopting a better fyftem of hufbandry.

It is conceived, that the idea of high rents being a fpur to improvement and exertion, is a common, and, to a certain extent, a juft maxim. No doubt there may be fome who, if they had the land for nothing, would be ruined by their indolence. But the more common cafe is, that when a tenant fees that all his exertions will not do, he becomes difpirited and defperate, and allows himfelf to be carried along by the ftream which he cannot ftem. The land fuffers, the tenant fails, the farm gets a bad name, and the rent muft be lowered. Thus the landlord, as well as the tenant, fuffers, by raifing the rent higher or fafter than the improvement of the land will bear. But he adds, that a fubftantial tenant is generally cautious of engaging to pay a rent that is exorbitant. He fees the fuccefs of thofe who inveft their money in other branches of bufinefs; and he follows their example, if he has not the profpect of a farm's yielding him full intereft for his money, and an adequate return for his diligence and labour. Whereas he who has leaft to lofe, is often the moft forward to offer, and the landlord is often tempted to accept the offer, without confidering that a capital is neceffary for paying the rent, and improving the land. Inftances of ruin to the tenant, and lofs to the landlord, from too high rents, are not unfrequent, efpecially on fome of the fmaller eftates. Moft of the farmers toil hard, live poorly; and for one who has a trifle for his pains, perhaps two give their pains for nothing. Many who have old leafes obtained before the late rife in land, and in its produce, took place, are very well, as are alfo many of thofe who have fheep ftocks; as their poffeffions are managed with lefs expence, and the value of fome of them was not well known till they were tried under the fheep fyftem. But even bad bargains are become good by the late rise on every article of produce; and most of those who have leases are at present at their ease.

It is concluded that the occupiers of land, whether in pasturage or tillage, ought certainly to be able, like labourers or tradesmen, to live by their occupation, and to support their families by their daily care and labour. The interest of money invested in their stock, with the proper allowance for tear, wear, and risk, they should be able to save as a provision for their families, and for old age; as the money so invested would give this return, if laid out on interest, without any trouble whatever. It cannot be considered as any part of the produce of the ground; and therefore no part of it ought, in equity, to enter into the payment of the rent; and yet not one in ten, perhaps, is able to save it; nor do they commonly advert that so much ought to be saved in justice. They are generally satisfied if they can keep their stock undiminished; so that the business, in general, returns much less to those engaged in it than almost any other. A happy predilection in favour of the occupation in which they were brought up, is, he thinks, what induces so many to follow it. Perhaps it may be also said, that there is implanted in the human mind, for wise purposes, a certain innate disposition, or instinct, which leads it to delight in rural occupations.

These remarks should be well attended to by the proprietors of farms, as their advantages, as well as that of their tenants, may be greatly promoted by such means.

In regard to the receiving of rents where they are of different kinds, as for cottages, tithes, in the form of compositions, chief rents, quit rents, and some other sorts, besides those of the farm kind, they require some attention and method, such as the fixing of distinct times in the same, or different days, for the reception of each, when on a large scale, so that the exact times of attendance for each may be known to those who have any thing to settle. So far as farm rents are concerned, the fixing of proper periods for receiving them is of great importance, though the matter has hitherto been little attended to, there being often no fixed time known to the holders, until signified by the precept of the receiver. And that is, in many cases, liable to alteration. This is very inconvenient to the farmers in many instances, as they must either sell their corn and live-stock to great disadvantage, many times, before it was necessary, and have large sums of money lying uselessly by them, or meet the receiver, perhaps, with only part of the rent. The propriety and necessity of having certain exact times for receiving rents are therefore evident, and, of course, the most suitable times for these are to be ascertained, as whatever enables the holders of land to turn their produce to the most advantage, increases the prosperity of the farms, and ultimately benefits the proprietor.

In this country it is said, by the author of the work on Landed Property, farm rents mostly become due at Lady-day and Michaelmas. But the proper times of paying them depend on the marketable produce of the land, and the season of the year at which it goes, and can be best sold in the markets. The holders of farms should never be forced to improper regulations in these respects, or be suffered to withhold the payment of their rents when they have obtained the money for their produce.

Upon corn farms, which are numerous in most parts of this country, Michaelmas is the most improper time in the whole year to call upon tenants for their rents. It is at the close or height of harvest, as the situation may be, when their pockets are drained by extra expensive labour, and when the grain cannot be threshed out to replenish them; also when much of the off-going live-stock is not ready for the market.

In the county of Norfolk the above writer paid great attention to this matter, and found that there, the latter end of February, or beginning of the succeeding month, was the most proper season for Michaelmas farm rents to be paid; and the month of June for those of Lady-day. And, by correct examinations, those most proper in other places may be found, keeping the above principles constantly in view. Farmers should never be obliged to do any thing improper in the disposal of their articles at unsuitable seasons or markets, or to raise money in any improper ways; nor be led into speculations with money while it lies idly by them.

The best seasons having been ascertained, the exact periods are to be fixed on, from the particular nature of the farms, the customs of the districts in respect to fairs and the dealers in different sorts of produce, which may generally be readily managed without much difficulty.

Rent *Accounts*, such as are kept on estates, whether of farms, cottages, chief rents, or any other sorts of annual payments, by the managers. They should be clear and comprehensive, containing every thing of importance about them, as their different circumstances may direct.

The management of the farms, in rent accounts, whether yearly or half yearly, must be the same as in the receiving rentals, as they appear on the general map; and as they naturally lie on the face of the estate, according to the ideas of the writer of the work on Landed Property. See Map *of Estates*.

The parishes, or manors, lying wholly or partially within the estate, are to be first geographically arranged, and then the farms on the same principle as they lie within the respective parishes. In this way it is constantly the same, and has the advantage of not being liable to be disturbed by changes of any sort, which affords much facility and convenience in all such accounts on many occasions.

Rent *Charges*, the fixed payments to which an estate or farm is subject to, such as chief rents, quit rents, annuities, endowments, schoolmasters' salaries, charitable donations, &c.

Rent *Days*, the particular days or times when the rents of estates or farms become due. They should, in all cases, be exactly and properly fixed as to season and other circumstances. See Rent.

Rent-*Roll*, a general statement of the gross annual income of an estate, or receivership, whether it arises from farms, woods, lands, quarries, cottages, or any other similar things; or from tithes, quit rents, or any other sort of rents, &c.

In forming rent-rolls, this sort of general view of income is best arranged, according to the writer of the work on Landed Property, in columns, as being the most plain and perspicuous; and for a schedule of farms, the following heads are proper. First, the numerals identifying the several farms in the general map. Secondly, the names of the farms. Thirdly, the contents or admeasurement of each. Fourthly, the names of the present holders. Fifthly, the amount of the existing rents. Sixthly, the amount of the outgoings, if any payable by the proprietor. And, seventhly, the expirations of the terms, if any. The farms should be arranged according to their situations.

In the receiving of rentals, they are the particulars. These are few where the rents are regularly paid, the farms under proper management, and the holders pay the taxes and repairs. But it may be necessary to see in the receiver, at one view, the name of the farm, and the name of the holder, as well as the amount of his half year's rent.

And

And where arrears are suffered, and, of course, accounts created, more particulars are necessary, such as the name of the farm and the tenant, his arrear at the last payment, his half year's rent, and any other charge that may be against him, as well as any allowance which is to be made to him, and the neat sum that is receivable—a blank being left for the sum received, and another for the arrear left. These things should be done in the manner of the best accountants, the arrangements being made in the same way as the rent-roll with an alphabetical index.

RENTA, in *Geography*, a lake of Albania, near Scutari.

RENTAL, a roll in which the rents of a manor are written and set down, and by which the lord's bailiff collects the same; it distinguishes the lands and tenements, and the names of the tenants, the several rents arising, and for what time, usually a year. See RENT-*Roll*.

RENTER WARDEN, an officer in most of the companies of London, whose business is to receive the rents or profits belonging to the company.

RENTERBACH, in *Geography*, a river of Saxony, which runs into the Elbe near Wittenberg.

RENTERIA, a town of Spain, in Guipuscoa; three miles S.E. of St. Sebastian.

RENTERING, FINE-DRAWING, in the *Manufactories*, the sewing of two pieces of cloth, edge to edge, without doubling them; so as that the seam scarcely appears at all: hence it is called *fine-drawing*.

The word is formed from the French, *rentraire*, which signifies the same thing; and which Menage, after Salmasius, derives from the Latin, *retrahere*, of *re*, *in*, and *trahere*, by reason the seam is drawn out of sight, and covered.

Serges, &c. are to be sewed: cloths fine-drawn. The author of one of the Let. Edif. et Cur., speaking of the great dexterity of the fine-drawers in the East Indies, assures us, that if you tear a piece of fine muslin, and give it one of them to mend, it shall be impossible for you to discover the place where it is rejoined, even though you had made a mark to know it by.

The dexterity of our own fine-drawers, though inferior to that above-mentioned, is nevertheless such, as puts them in a condition to defraud the king, by sewing a head or slip of English cloth on a piece of Dutch, Spanish, or other foreign cloth; or a slip of foreign cloth on a piece of English, so as to pass the whole, as of a piece; and by that means avoid the duties, penalties, &c. The trick was first discovered in France by M. Savary, author of the Diction. de Commerce.

To renter, in *Tapestry*, is to work new warp into a piece of tapestry damaged, eaten by the rats, &c. and on this warp to restore the ancient pattern, or design. The warp is to be of woollen, not linen. Among the titles of the French tapestry-makers, is included that of renterers.

Fine-drawing is particularly used for a rent, or hole, happening in the dressing or preparing of a piece of cloth, artfully sewed up or mended with silk.

All fine-drawings are reputed defects or blemishes; and ought to be allowed for in the price of the piece. Hence, M. Savary establishes it as a rule, which is certainly founded on natural equity, that every manufacturer mark the fine-drawings of his cloth with a piece of packthread tied to the list; to direct the draper to the spot: and that the draper apprize the taylor, or other person to whom he sells it, of the same, that he may not come to damage in the cutting; there being instances of drapers condemned to take back their cloth, when cut to pieces, for omitting to mention the fine-drawings, and other flaws.

On this occasion, M. Savary extols the procedure of an English merchant, who, sending a piece of cloth damaged in one spot, to his correspondent at Paris, put a piece of gold in the damaged place, to make up the damage. But as this example is perhaps the only one of its kind, that author recommends it to the merchant, or draper, to unfold all the pieces entirely, as they come to him; to discover the fine-drawings, and other flaws, in order to make the clothier accountable for them.

RENTERSHAUSEN, in *Geography*, a town of the duchy of Wurzburg; 7 miles E. of Lauringen.

RENTOWN, a town of Scotland, in Dumbartonshire, considerable for its manufactures; 5 miles W. of Dumbarton.

RENTRE'E, Fr. in *Music*, a return to the subject of a musical composition, after a pause, or some excursion or deviation from the theme; or in a fugue, an imitation of some particular passage or design.

RENTY, in *Geography*, a town of France, in the department of the straits of Calais, on the Aa; 9 miles S.S.W. of St. Omer.

RENTZ, a town of the island of Rugen; 11 miles S.S.W. of Bergen.

RENUENTES, in *Anatomy*, a pair of muscles of the head, thus called as being antagonists to the annuentes; and serving to throw the head backward, with an air of refusal.

From their situation they are also called rectus capitis, major et minor.

RENVERSE', Fr. in *Music*. With respect to intervals inverted, this term is opposed to direct. (See DIRECT.) With respect to chords, it is opposed to *fundamental*; which see.

RENVERSE', *inverted*, in *Heraldry*, is when any thing is set with the head downward, or contrary to its natural way of standing: thus, a chevron renversé is a chevron with the point downwards.

The same term they also use when a beast is laid on its back.

RENVERSED VOLTE. See VOLTE.

RENVERSEMENT, Fr. in *Music*, an inversion in the order of sounds which compose the chords, and in the parts which constitute the harmony: which is done by substituting, by octaves, treble notes for the base, and base notes for the treble. It is certain that every common chord has a fundamental and natural order pointed out by the harmonics of a single string, a great bell, or organ pipe. (See HARMONICS, and RESONANCE.) But the circumstances of the succession, taste, expression, selection of notes for melody, variety, approximation of the harmony, frequently oblige a composer to change this order, by inverting the chords, and consequently the disposition of the parts. As any three things may be arranged in six different ways, and four things in twenty-four ways, it seems at first as if a common chord was susceptible of six changes, and an accompanied discord of twenty-four; as the one is composed of three sounds, and the other of four; and that the inversion only consists in the transposition of octaves. But it must be remembered, that in harmony a change in the upper parts is not regarded as an inversion, provided the base or fundamental sound remains the lowest. Thus, these two orders of sounds, C*eg*, or C*ge*, are not regarded as inversions of the harmony. And in the chord of the 7th no change in the upper parts constitutes an inversion.

As long as the fundamental sound is the lowest part, the order is direct. But when this order is changed, or the fundamental sound is given by transposition to one of the upper parts, the harmony is inverted. In whatever part a discord is prepared, it must be resolved by the same part;

a sharp

a ſharp 7th muſt aſcend, a flat 7th muſt deſcend; falſe relations muſt be avoided. This is the key to the chief myſteries of compoſition. Binding notes in ſyncopation in the treble and baſe muſt be differently treated: in the 9th the chord is direct; in the 2d it is inverted, the diſcord being in the baſe.

Upon the organ, and other keyed-inſtruments, inverſions are neceſſarily made for the convenience of the hand, in giving different faces to the ſame chord. See FACE.

RENVERSING. See REVERSING.

RENUKA, or RENUCI, in *Mythology*. See RUNEKA.

RENUNCIATION, RENUNCIATIO, the act of renouncing, abdicating, or relinquiſhing any right, real or pretended.

Renunciations are ſometimes *expreſs*, as by contracts, &c.; ſometimes *tacit*, as by contrary acts.

To renounce an inheritance, a community, &c. is to paſs a ſolemn act before a notary, or public officer, by which a perſon declares he will not intermeddle in an inheritance, or profit in a company; but ſurrenders his part, and quits all pretenſions.

RENVOI, Fr. in *Muſic*, a reference to a ſtrain, or part of a ſtrain that is to be repeated; either implied by dots in the ſpaces of the ſtaff, or by an $\dot{S}$ dotted, which is the initial of *ſegno*, Ital. a ſign. See REPEAT.

RENWEZ, in *Geography*, a town of France, in the department of the Ardennes, and chief place of a canton, in the diſtrict of Mézières; 7 miles N.W. of Mézières. The place contains 1202, and the canton 6061 inhabitants, on a territory of 140 kiliometres, in 16 communes.

REOLLE, LA, a town of France, and principal place of a diſtrict, in the department of the Gironde. N. lat. 44° 35′. E. long. 0° 2′.

REORDINATION, REORDINATIO, the act of conferring orders on one already ordained.

The ceremony of ordination impreſſes what the divines call an indelible character; and cannot, therefore, be repeated: yet is reordination practiſed in England, with regard to the diſſenting miniſters, who conform to the church; the biſhops pretending that they alone have a right to confer holy orders, and that every prieſt or miniſter, who does not receive them at their hands, has no lawful or regular vocation.

This has formerly proved a great obſtacle to the re-union of thoſe miniſters to the church of England; many of whom, otherwiſe diſpoſed to conform, have ſcrupled to be re-ordained; inſomuch as re-ordination implies their former vocation to be null; that they had adminiſtered the ſacraments without any right thereto; and that all their miniſterial acts were invalid.

In the 11th century, the crime of ſimony having been very flagrant, many people fell into the error to believe, that the ſimoniacal biſhops could not ordain validly, and thoſe who had received orders at their hands ſhould be reordained. The people of this opinion made a party of themſelves, and were diſtinguiſhed by the title of "Reordinantes."

REORTHE, LA, in *Geography*, a town of France, in the department of the Vendée; 13 miles W. of Châtaigneraye.

REPAIR *a Statue, To*, or other piece of ſculpture, is to touch up a ſtatue, &c. (caſt in a mould) with a chiſſel, graver, or other inſtrument, to finiſh the places which have not come well off.

To REPAIR *a Caſt*, figure, or the like, they clear off the barb, and what is redundant in the joints and projectures. See STATUE.

To REPAIR *a Medal*, is to retouch it; ſo as, from ruſty and defaced as it was, to render it clean, neat, and perfect. In order to this, they take off the ruſt with a graver, touch up the letters, poliſh the ground, and raiſe and reſtore the figures which before were ſometimes ſcarcely ſeen. When the figures are eroded or broken, they ſit a piece of cement on the ſpot; and on this cut with a graver ſo dexterouſly, that the figures appear entire, and well kept; yet nothing ſpoils medals ſo much as repairing them. See MEDAL.

To REPAIR *a Ship*, is to amend any injuries, or ſupply any deficiencies, which a ſhip may have received by age, battle, tempeſtuous weather, &c. The repair is neceſſarily greater or ſmaller in proportion to the loſs or damage the veſſel has ſuſtained. Accordingly a ſuitable number of the timbers, beams, or planks, or a ſufficient part of either are removed, and new pieces fixed in their places. The whole is completed by *breaming*, *calking*, and *paying* the body with a new compoſition of ſtuff.

REPAIRERS, artificers who chaſe figures and beautify ſword-hilts, &c.

REPAIRING, in *Building*, *&c.* See REPARATION, and RESTAURATION.

The repairing of large walls, doors, ceilings, coverings, &c. belongs to the proprietor or landlord: the tenant is only charged with ſmall repairs, as glaſs windows, locks, &c. by the French called *locative* repairs.

REPAIRS, in *Hunting*, are the haunts and places which the hare runs to.

REPAIRS *of Farm Buildings*, in *Rural Economy*, the neceſſary means of putting and keeping them in proper order. This properly belongs to different ſorts of workmen, as maſons, carpenters, &c. It is a bad practice to let buildings of this nature fall much into decay, as by ſuch neglect a great deal of expence is frequently incurred that might otherwiſe have been avoided. See FARM-*Buildings*.

REPANDUM FOLIUM, in *Botany*, a leaf whoſe outline is undulating, without the ſurface, or ſubſtance, being otherwiſe than even. See LEAF, where, for *nyphæoides*, read *nymphæoides*.

REPARANDIS PONTIBUS. See PONTIBUS.

REPARATION, REPARATIO, the act of repairing, reeſtabliſhing, retrieving, or mending a building, or other work, damaged, or gone to decay.

The enemy repaired the breach as ſoon as it was made. The eſtabliſhment of turnpikes is for repairing of the roads. An eccleſiaſtical patron is by ancient cuſtom obliged to repair the choir or chancel of a church, and the pariſhioners the nave.

REPARATIONE FACIENDA, in *Law*, is a writ which lies in divers caſes, *e. gr.* where there are tenants in common, or joint tenants of a houſe, &c. which is fallen to decay, and the one being willing to repair it, the other two will not; in this caſe, the party willing ſhall have this writ againſt the other two.

REPARO, in *Geography*, a ſmall iſland near the coaſt of Braſil. S. lat. 29° 23′.

REPART, in the *Manege*, is to put a horſe on, or make him part a ſecond time.

REPARTEE. See REPARTY.

REPARTITION, REPARTITIO, a dividing or ſharing a thing a ſecond time.

REPARTY, or REPARTEE, a ready, ſmart reply: eſpecially in matters of wit, humour, or raillery.

The word in the original French, *repartie*, has the ſame ſignification.

Wicquefort obſerves, that there is a great difference between

between a free, fprightly reparty, and an offenfive *farcafm;* which fee.

REPAST, Repastum, a meal or refection, taken at a ftated hour.

In old law-books repaft is particularly ufed for a meal's meat given to fervile tenants, while at work for their lord.

The French call their meal *repaft;* the Latins, *paftus;* the Italians and Spaniards, *pafto.*

In antiquity the repafts were frequently facrifices; for which reafon we find them often prepared by kings themfelves.

REPEALING, in *Law,* the revoking or annulling of a ftatute, deed, or the like. See Abrogation, Revocation, &c.

No act of parliament fhall be repealed in the fame feffion it was made in. A deed or will may be repealed for a part, and ftand good for the reft.

Brook ufes the word *repellance* in the fame fenfe.

REPEAT, in *Mufic,* a character fhewing that what was laft played or fung muft be repeated, or gone over again.

The repeat ferves inftead of writing the fame thing twice over. There are two kinds of repeats; the *great* and the *fmall.*

The *great* repeat is only a double bar, dotted on each fide; or two parallel lines drawn perpendicular acrofs the ftaff; with dots on either hand. See its form under Characters *of Mufic.*

This mark fhews, that the preceding ftrain is to be repeated; that is, if it be near the beginning of the piece, all hitherto fung or played is to be repeated; or, if towards the end of a piece, all from fuch another mark.

In gavots, we ufually find the repeat at about the third part of a piece; in minuets, borees, courants, &c. towards the end.

Some make this a rule, that if there be dots on each fide the bar, they direct to a repetition both of the preceding and the following ftrain; if there be only dots on the fide, then only the ftrain on that fide is to be repeated.

The *fmall* repeat, is where only fome of the laft meafures of a ftrain are to be repeated: this is denoted by a character fet over the place where the repetition begins (fee Characters, in *Mufic*), and continues to the end of the ftrain.

When the fong ends with a repetition of the firft ftrain, or part of it, inftead of a repeat, they ufe the word *da capo, i. e.* from the beginning.

REPEATING Circle, an inftrument ufed in *Navigation, Aftronomy,* and *Surveying.* This inftrument derives its name from the property it has of giving the average of feveral repeated meafures of an angle, made round the whole circle, fo as to diminifh the errors of divifion and of excentricity; which is a very ufeful property, where the art of dividing is not brought to that perfection which it is in England. When the lunar method of determining the longitude, by the help of improved tables of the moon's motion, was propofed to be put in practice, Mayer offered a conftruction of the circle, which, by repeating the meafure of a lunar diftance, promifed to increafe the accuracy with which fuch diftance could be meafured; and after him, Borda went a ftep farther towards the attainment of the defired object, both whofe contrivances we have defcribed under our article Circle. Thefe inftruments, like Hadley's octants, meafured the angles by reflection, and were confequently ufed at fea; but the principle of repetition is not confined to reflecting inftruments; and Borda conftructed, or contrived the conftruction of, a repeating circle, which will meafure either vertical or horizontal angles without reflection, with a degree of accuracy that has placed it high in the eftimation of the French, among whom accurate dividing is yet a defideratum. This inftrument we have alfo defcribed, and likewife Troughton's improvement on it, in the article already referred to.

But the repeating principle was extended by Jofeph de Mendoza Rios in the reflecting circle, fo as to meafure both backwards and forwards, and to give *double* refults by means of a moveable or *flying* circle, which we have likewife defcribed under the article Circle, together with our obfervations on the peculiarities of its conftruction. It remains, therefore, that we now defcribe a recent conftruction of a reflecting and repeating circle, contrived by profeffor Hafsler of Philadelphia, who is a native of Switzerland, and who has refided feveral months in London, for the purpofe of collecting fuperior aftronomical and furveying inftruments, at the expence of the American government. The object of this ingenious foreigner was to unite the repeating principle of Borda, with the firm conftruction of Troughton's reflecting circle, fo that his new inftrument might be free from the objections of the repeating circles that preceded it, arifing from fhallow centre-work, and clamping after the contacts were made in an obfervation; and in the conftruction he has adopted, by the aid of Troughton, he has rendered his inftrument free from thefe objections, and given it every advantage which its original contriver contemplated: we cannot, however, admit, that in practice it is fuperior in accuracy, and certainly not in fimplicity, to Troughton's *reflecting circle,* which we have before defcribed, as giving the average of fix readings at two operations, in inverted pofitions, at the different fides of zero on the fixed circle. The union of Borda's and Troughton's conftructions is thus effected by Hafsler; the circular border of Troughton's inftrument is made moveable round the centre, like his three armed verniers, and is graduated like his, while a pair of oppofite verniers move round the fame centre, above the plane of the moveable or flying circle, having a clamping apparatus for flow motion at one of the two oppofite verniers, fo that the pair of verniers may be made to revolve with or without the graduated flying circle; another pair of verniers, fimilar to the former, and having alfo a clamping apparatus for flow motion, are made faft to the frame, and have the extreme ends of their connecting diametrical bar united by a graduated femicircle, that lies under the flying circle, and is hid thereby when the graduated face of the circle is uppermoft; the ufe of this femicircle is, to receive a pair of fliding pieces of brafs that act as ftops to the indices, when they are properly placed at the rough angle, to the right and left of zero on the flying circle, by a previous operation; fo that, when the bar of the verniers comes in contact with either of thefe ftops, it is known, even in the dark, that the place where a contact is to be made is nearly afcertained, and the vernier-bar may be made faft, for the fcrew of flow motion to be brought into action to complete the contact. The principle on which the meafurement is effected is this; the revolving verniers move forward from zero of the graduated circle, when the ftops are previoufly fet to the rough angle, till the index or vernier-bar touches the ftop to the left, when the graduated face is uppermoft, and is clamped to the fixed verniers; the clamping apparatus then fixes the verniers, and the tangent-fcrew completes the contact; the two revolving verniers might now give the angle, by two readings, but the repeating principle has not yet been introduced, and confequently no advantage is yet derived from this firft obfervation, over a common circle with a double vernier; the fixed verniers are in the next place unclamped, but as they have no motion, the flying circle and revolving verniers are brought back to the right together, acrofs the point zero, till

till the vernier-bar touches the fecond ftop, and during this motion, the revolving verniers have moved backwards juft *double* the rough diftance with the attached circle, that they did forwards before without it; confequently the fixed verniers will now read the fame angle at the right of zero, that the revolving verniers did on the left, when the clamping is again made and the contact completed; but ftill this is only a fecond mode of reading a fingle meafure of the angle, and nearly all that is yet gained in accuracy, is the extermination of the index error, and that of the dark glafs, if ufed; thefe errors having been alternately pofitive and negative, if any exifted. Thefe two meafures, feparately read, are equivalent to Borda's *croffed* obfervation, as he calls it, becaufe the motion of the vernier-bar *croffes* the point zero in his fixed circle: here it is prefumed that the two objects, that include the angle, are equally luminous; but if not, it will be neceffary to invert the face of the inftrument before each fecond, fourth, fixth, &c. contact, and then the motions will all be forward, or from right to left, which otherwife would be alternate: the fecond reading, however, may be omitted; the revolving verniers, being unclamped, muft be moved again to the firft ftop in the original pofition, where, the contact being complete, they will give a *double* meafure if examined; but the readings are yet omitted: the fixed verniers are now unclamped, the inftrument again inverted, and the contact completed, when thefe verniers, if examined, will alfo give double meafures; and thus treble and quadruple meafures muft be had fucceffively at both the revolving and fixed verniers, or even more, if the circle has not been paffed over by each pair of verniers, before the readings are required to be examined, and then the average of all the meafures by the fixed verniers, added to an average of all the meafures by the revolving verniers, will afford the means of getting an average of the whole number of meafures.

From this defcription of Hafsler's mode of applying the repeating principle, it will be obvious to the reader, that the diametrical bars of the two pair of verniers muft not be contiguous to each other, when the glaffes called the horizon-glafs and index-glafs are parallel; and accordingly we find, on examining an inftrument of this conftruction, that thefe bars crofs one another at right angles before the operations begin; but as there is but one zero in the circle, one pair of the verniers muft neceffarily begin at 90°, when the other pair begins at 0; confequently ninety degrees muft be deducted from the fum of the meafures of this pair before their average is taken: otherwife, if neither pair of the verniers begin at zero, the two numbers from which they refpectively commence muft both be deducted before the averages are taken, in which cafe it will be of no importance at what part of the flying circle the operations begin. Should the reader find any difficulty in comprehending this defcription of Hafsler's repeating circle, without a reference to a drawing, we recommend that he refer to our account of reflecting circles, defcribed under the article CIRCLE, where he will find the account of the two feparate inftruments of which this forms an union; and at the fame time will fee how it differs from Mendoza's, which gives *double* refults.

By way of illuftrating the ufe of Hafsler's repeating circle, we will fuppofe that fome known ftar is to the eaft or weft of the moon, and that the longitude of the place of obfervation is required from an actual meafurement of the diftance of the faid ftar from the moon's limb, when compared with its computed diftance as given for a certain hour on the fame evening at Greenwich, in the Nautical Almanac: we will fuppofe the glaffes of the circle adjufted, and the fmall telefcope fcrewed into its focket, and fo adjufted both for diftinct vifion, and comparative brightnefs of both objects, that the ftar can be brought to touch the moon's limb, and have a fenfible contact; in the firft place, hold the plane of the circle in fuch an inclined pofition that it may pafs through both objects, and get the ftar into the field of view, while the revolving verniers are at zero, and the fixed ones clamped at 90°; in the next place, move the revolving verniers with an equable motion, and let the eye follow the ftar, or rather the image of it, till it comes to the edge of the moon, which it may be made to approach by a proper motion of the body; then clamp the index there till the ftop is put on the femicircle very nearly to touch the edge of the index, where it muft remain; the fecond ftop muft alfo be put to the fame divifion on the femicircle at the other fide of its zero, provided this zero be co-incident with the zero of the circle; or, which is the fame thing, the diftance between the ftops muft be fomewhat more than double the angle to be meafured; the contact may now be completed by the tangent-fcrew; let the fixed verniers be unclamped, and the releafed circle and revolving verniers be made to recede together till the fecond ftop gives them a check, there they muft be clamped and the circle inverted, when the ftar will again be feen nearly in contact, which muft now be made entirely fo by the fcrew of flow motion; in the next place the moveable verniers, being firft unclamped, muft be carried again to the firft ftop and clamped, to make the contact as before, after the inverfion of the circle has again taken place; and in this manner the revolving verniers muft be moved to the firft ftop, and the verniers and circle together to the fecond ftop, before each inverfion and contact, till five, fix, feven, or more alternate operations have been gone through, and the whole circle has been travelled over, which may always be known from the pofition of the ftops. The exact times muft be noted at the beginning and end of thefe operations, which by an expert obferver will be gone through in a few minutes, and the mean time will be had of the moment correfponding to the mean of the repeated obfervations: at thefe times the affiftants muft alfo take each their two altitudes. Say now that the ftops were required to be nearly at 40° at each fide of zero of the femicircle, or that the diftance between them was 80°, within a few minutes over, and that there were nine obfervations thus made with the revolving verniers, and eight with the fixed ones, which numbers fuppofe the firft and laft meafures to be taken with the fame pair of verniers, or with the fame face of the circle uppermoft; fay alfo, that the final readings by this pair of verniers were refpectively 1° 10′ 20″, and 181° 10′ 0″, or rather 361° 10′ 20″, and 541° 10′ 0″, becaufe thefe verniers completed the entire circle; then if we diminifh the latter reading by 180°, its diftance before the other, we fhall have 361° 10′ 0″, and the average of the pair of oppofite verniers will be 361° 10′ 10″, which quantity divided by 9, the number of meafures taken by them, will give a quotient of 40° 7′ 8″.9 for the firft average of the diftance, refulting from the operation of the revolving verniers alone; again, let the final readings of the fixed verniers be refpectively 50° 57′ 20″ and 230° 57′ 30″; but if we increafe the firft reading by 360°, we fhall have 410° 57′ 20″, which muft be diminifhed by 90°, becaufe it ftarted from this number, and the remainder will be the correct reading, namely 320° 57′ 20′; alfo 230° 57′ 30″ increafed by 360° is 590° 57′ 39″, and this number diminifhed firft by 90°, as before, and then by 180°, the diftance by which it precedes its fellow-vernier, will be 320° 57′ 30″, and confequently the average of the two final readings of the fixed verniers will be 320° 57′ 25″, which fum divided by 8, the number of repeated

peated meafures in the inverted pofition, will give a quotient of $40° 7' 10''.6$ for the diftance averaged by the fixed verniers; and laftly $\frac{40° 7' 8''.9 + 40° 7' 10''.6}{2} = 40° 7' 9''.75$, the exact *apparent* diftance, which may be converted into the *true* diftance by any of the methods ufed for clearing it of the joint effect of *parallax* and *refraction*. See Longitude, and Lunar *Obfervations*.

Repeating *Mechanifm*, in *Horology*, is a mechanical contrivance that, when acted on by a pull or pufh, will make the ftriking part of a clock or watch repeat the hours and quarters of exifting time, fo that a perfon in the dark, or even in bed, may know within a quarter of an hour what it is o'clock, as well by night as by day. The firft contriver of the repeating mechanifm of a clock was Barlow, a London clock-maker, who in the year 1676 produced to the world his fpecimen of ingenuity, which aftonifhed all the admirers of the mechanical arts, and excited in others a defire to vary the conftruction, with a view to the improvement of the original contrivance; and the confequence has been, that Quare, Tompion, and others in London, as well as after them Julien le Roy, Thiout, Collier, Larçay, Berthoud, &c. on the continent, have given fo many different kinds of repetition, for both clocks and watches, that a particular defcription of each conftruction would require feveral plates, and a whole volume to give the details. Under our article Clock we have already explained at confiderable length the particulars of the repeating mechanifm of two feveral clocks, as it is conftructed at this time, from which the reader will fee how the acting parts may be varied in many ways to anfwer the fame purpofe; but in moft of the modern contrivances the *rack* and the *fnail* conftitute the bafis of the plan, and regulate the action of all the metallic parts employed. For the repeating mechanifm of a watch, fee our article Watch.

REPELLENT Medicines, are thofe which prevent fuch an afflux of fluids to any part as would excite tumour or inflammation, or which tend to diminifh fuch an afflux, when it is already produced. Medicines of this quality are principally refrigerants and aftringents, efpecially the former. The moft effectual repellent is cold; and thofe applications, therefore, which moft effectually obftruct the heat, are the moft efficacious repellents; and many of the drugs, which are applied in combination with cold liquids, are of little value; the cold menftruum, that is the water, being the principal agent in the curative procefs.

REPELLING Power, *vis repellens*, in *Phyfics*, is a certain power or faculty refiding in or exerted by the minute particles of natural bodies, by which, under certain circumftances, they mutually fly from each other.

This power is the reverfe of the attractive power.

Sir Ifaac Newton having eftablifhed the attractive power of matter from obfervation and experiment, argues, that, as in algebra, where pofitive quantities ceafe, there negative ones commence; fo in phyfics, where the attractive force ceafes, there a repelling force muft begin; and adds, that there is fuch a force, does likewife appear from obfervation.

As the repelling power feems to arife from the fame principle as the attractive, only exercifed under different circumftances, it is governed by the fame laws: now the attractive, we find, is ftronger in fmall bodies than in great ones, in proportion to the maffes; therefore the repelling is fo too. But the rays of light are of all others the moft minute bodies we know of; therefore, of all others, their repelling force muft be the greateft.

Sir Ifaac Newton computes, that the attractive force of the rays of light is above 1000000000000000 times as ftrong as the force of gravity on the furface of the earth: hence arifes that inconceivable velocity with which light (if it confift of real particles) muft move, to reach from the fun to our earth in feven minutes. For the rays emitted from the body of the fun by the vibrating motion of its parts are no fooner got without the fphere of attraction of the fun than they come within the action of the repelling power.

The elafticity or fpringinefs of bodies, or that property by which, after having their figure altered by an external force, they return to their former figure, follows from the repelling power. See Repulsion.

REPENTANCE, in *Theology*, is a change of fentiments followed by a change of conduct: or repentance denotes fuch a conviction of the evil and danger of a finful courfe, as is fufficient to produce fhame and forrow in the review of it, and effectual refolutions of amendment. This definition expreffes the fenfe of the two words μεταμελεια and μετανοια, which are commonly ufed by the evangelical writers to fignify repentance.

REPENTIGNY, in *Geography*, a town of Canada, on the river St. Laurence. N. lat. 45° 48'. W. long. 73° 15'.

REPERCUSSION, in *Mechanics*. See Reflection.

Repercussion, in *Mufic*, iteration, a repetition of the fame note or found.

This often happens in the modulation, where the effential chords of each mode, or of the harmonical triad, are to be ftruck oftener than the reft; and of thefe three chords, the two extremes, *i. e.* the final and the predominant one, (which are properly the repercuffions of each mode) oftener than the middle one.

REPERNDORF, in *Geography*, a town of the duchy of Wurzburg; 7 miles S.E. of Wurzburg.

REPERTORY, Repertorium, a place in which things are orderly difpofed, fo as to be eafily found when wanted.

The indices of books are repertories, fhewing where the matters fought for are treated of. Common-places are a kind of repertories, very ufeful to the learned.

Repertorium *Anatomicum*, denotes a large hall near an amphitheatre of diffections, where fkeletons, both human and brutal, are orderly preferved. Such is the repertory in the French king's garden at Paris.

REPETEND, in *Arithmetic*, is ufed for that part of an indetermininate or infinite decimal fraction, which is continually repeated ad infinitum.

Thus, in the indeterminate decimal fraction 317.45 316 316,316, &c. the figures 316 are called the repetend.

Thefe repetends often arife in the reduction of vulgar fractions to decimals, thus $\frac{1}{3} = 0.3333$, &c. $\frac{1}{7} = 0.142857$, 142857, &c. $\frac{1}{11} = 0.09\,09, 09$, &c.

Decimals of this kind are called repeating or circulating *decimals*, (which fee,) on account of this continual repetition or circulation of the fame figures. Infinite decimals are of two kinds, which may be diftinguifhed by the general denominations of certain and uncertain. A general infinite decimal is fuch whofe numerator runs into infinity by a continual repetition of one or more figures, as 44, &c. 033, &c. Uncertain decimals are fuch, whofe numerator goes on for ever without a conftant circulation of figures. The effential difference between thefe two kinds is this; that the certain infinite decimals have a determinate, finite, and certain value, in that there is a certain determinate vulgar fraction, which expreffes the true and complete value of that infinite decimal, whereas the uncertain have no fuch finite and affignable value: and hence the reafon of the names.

Repetend, *Single*, is that where only one figure is repeated, as in 0. 3 3 3, &c.

Repetend, *Compound*, is that where two or more figures are repeated, as in 0. 09 09, &c. or in 0. 142857 142857, &c.

Decimals with repetends may always be reduced to vulgar fractions; for either the repetend begins with the decimal, or not.

If the repetend begins with the first place of decimals, or if the decimal is a pure circulate, make it the numerator of a vulgar fraction, and make the denominator consist of as many 9's as the repetend has figures; or if there be cyphers between the point and repetend, with as many cyphers to the right hand of the denominator, then will this vulgar fraction be equal to the decimal.

Thus, if the repetend be single, as in 0. 3 3 3 3, the vulgar fraction equal to it will be $= \frac{3}{9} = \frac{1}{3}$. So if the repetend be compound, as in 0. 09 09, &c. the equivalent vulgar fraction will $= \frac{09}{99} = \frac{9}{99} = \frac{1}{11}$.

And in like manner 0. 142857 142857, &c. $= \frac{142857}{999999} = \frac{1}{7}$.

The reason is obvious from this consideration, that the decimal 0. 3 3 3, &c. is $= \frac{3}{10} + \frac{3}{100} + \frac{3}{1000}$, &c. the sum of which will be equal to $\frac{3}{10}$ divided by $1 - \frac{1}{10} = \frac{3}{9} = \frac{1}{3}$; and so of the rest.

If the repetend does not begin with the first place of decimals, but at some place farther on towards the right, or if it be a mixed circulate, as in the decimal 0. 8 3 3 3, &c. where the repetend does not begin till the second place of decimals, observe, that 0. 8 3 3 3 + &c. $= \frac{8}{10} + \frac{3}{100} + \frac{3}{1000} +$ &c. $= \frac{8}{10} + \frac{1}{10} \times \frac{3}{10} + \frac{3}{10^2} +$ &c. But $\frac{3}{10} + \frac{3}{10^2} +$ &c. $= \frac{3}{9} = \frac{1}{3}$, as before: therefore the proposed decimal is $= \frac{8}{10} + \frac{1}{10} \times \frac{1}{3} = \frac{8}{10} + \frac{1}{30} = \frac{24+1}{30} = \frac{25}{30} = \frac{5}{6}$.

Thus also if the decimal 0. 2 27 27, &c. were proposed, we shall find it $= \frac{2}{10} + \frac{1}{10} \times \frac{27}{100} + \frac{27}{100^2} +$ &c. And $\frac{27}{100} + \frac{27}{100^2} +$ &c. being $\frac{27}{99} = \frac{3}{11}$, the decimal will be $= \frac{2}{10} + \frac{1}{10} \times \frac{3}{11} = \frac{2}{10} + \frac{3}{110} = \frac{22+3}{110} = \frac{5}{22}$. The reason of which is obvious from what has been said.

It may, perhaps, be worth while to observe, that if the numerator of a vulgar fraction be unity, and the denominator any prime number, except 2 and 5, the decimal equal to the proposed fraction will always be a repetend, beginning at the first place of decimals; and this repetend must necessarily be a submultiple, or an aliquot part of a number expressed by as many nines as the repetend has figures; that is, if the repetend have six figures, it will be a submultiple of 999999; if four figures, it will be a submultiple of 9999, &c. From whence it follows, that if any prime number be called p, the series 9999, &c. produced as far as is necessary, will always be divisible by p, and the quotient will be the repetend of the decimal fraction $= \frac{1}{p}$. For the management of decimals of this kind, see Malcolm's Arithmetic, book v. chap. 4.

REPETITION, Repetitio, the reiterating of an action. See Reiteration.

Habits are acquired by the frequent repetition of actions.

School-philosophers call the repetition of the same numerical effect, in another place, the replication of that effect.

Repetition. The French make use of this word for a *rehearsal*, which the Italians call a *prova*. "Rehearsals (says Rousseau) are necessary for compositions that are to be performed in public, in order to prove whether the several parts are correctly copied, and for ascertaining the entrances and the exits of the several characters, as well as to see that they seize the spirit of their parts, and of the entire drama. Rehearsals are likewise of use even to the composer himself, to enable him to judge of effects, and to make such changes as may seem necessary."

Repetition, in *Music*, denotes a reiteration or playing over again the same part of a composition, whether it be a whole strain, or part of a strain, or a double strain. The repetition is denoted by a character called a *repeat;* which is varied so as to express the various circumstances of the repetition.

Repetition, *Reply*, is also used when, after a little silence, one part repeats or runs over the same notes, the same intervals, the same motions; in a word, the same song, which a first part had already gone over during the silence of this.

Repetition, *Reply*, is also a doubling or trebling, &c. of an interval, or reiteration of some concord or discord.

Thus, a fifteenth is a repetition of the octave, *i. e.* a double octave, or second octave.

Repetition *of Passages*. See Rosalia.

Repetition, in *Rhetoric*, is a figure by which the orator rehearses the same words or phrases over again.

Of this there are two kinds. In the first, the word is repeated precisely in the same sense: as, *Oh, Jerusalem, Jerusalem, who killest the prophets*, &c. *My God, my God, why hast thou forsaken me?*

Such repetitions have the same effect in discourse, with second strokes of the pencil in painting; they render the colours more strong and lively.

Sometimes the orator begins again and again with the same word, of which we have an instance in the beginning of Cicero's first oration against Catiline: *Nihilne nocturnum præsidium palatii, nihil urbis vigiliæ, nihil timor populi, nihil consensus bonorum omnium, nihil hic munitissimus habendi senatus locus, nihil horum ora vultusque moverunt?* Where the word *nihil* so often reiterated gives an admirable force and vehemence to the discourse. Again, the same author: *Quem senatus damnârit, quem populus R. damnârit, quem omnium existimatio damnârit, cum vos sententiis vestris absolvetis?* Again, *Non feram, non patiar, non sinam.*

The second kind of repetition, called πλοκη, *place,* (which see,) is a repetition of the same word in the same phrase; but in such a manner, as that some new idea or character is added to the word in the second, which it had not in the first.

As, *Corydon is always Corydon: Ex illo Corydon Corydon est tempore nobis;* by which we signify, that Corydon is no ordinary person; and that nothing can distinguish him but the repetition of his own name: as if we should say, *he is Corydon, that is enough.* By the same figure our Saviour speaks, when he says: *Let your language be yea, yea; and nay, nay.* See Recapitulation.

REPETITUM, or *Vetitum Namium*, in *Law*. See Namium.

REPHAM, or Reepham, in *Geography*, a market-town and parish in the hundred of Eynsford, and county of Norfolk, England, is situated at the distance of 13 miles N.W. by N. from Norwich, and 112 N.E. by N. from London. The charter for its market, which is held on Saturday weekly, was obtained by sir John de Vaux, in the fifth year of the reign of king Edward V. An annual fair, on the 29th of June, was granted at the same time. At one period this parish was remarkable for having three churches situated within one sepulchral inclosure; *viz.* Reepham, Whitwell, and Hackford; but only two of these are now standing. The

The church of Reepham serves also for the village of Kerdeston, which belongs to the same lords. In this edifice was formerly a "famous image of the Virgin Mary," which, like the shrine of Diana at Ephesus, was productive of no small gains to its possessors; numerous pilgrimages having been made to it by persons of rank and affluence. Here are several monuments to the memory of different branches of the Kerdeston family. One of them, placed against the north wall of the chancel, bears the figure of a knight templar in armour, with his hands and legs crossed. It has no inscription, but is traditionally said to have been raised in honour of sir Fulk de Kerdeston, who died in 1270. Blomefield's History, &c. of Norfolk. Beauties of England and Wales, vol. xi. by John Britton, F.S.A.

REPIN, a river of Poland, which runs into the Dnieper, near Kiev.

REPITZ, or Ropitz, a town of Saxony, in the margravate of Meissen: 2 miles N. of Torgau.

REPLANTING, in *Gardening*, the act of planting a second time.

The gardeners used to displant their tulips every year, and replant them. Lettuces must be displanted and replanted yearly, to make them head and knit. If strawberries, &c. be not displanted and replanted once in a few years, they degenerate.

REPLEADER, Replacitare, in *Law*, is to plead over again what was once pleaded before.

If, by the misconduct or inadvertence of the pleaders, the issue be joined on a fact totally immaterial, or insufficient to determine the right, so that the court upon the finding cannot know for whom judgment ought to be given, the court will after verdict award a repleader, *quod partes replacitent;* unless it appears from the whole record that nothing material can possibly be pleaded in any shape whatsoever, and then a repleader would be fruitless. (4 Bur. 301, 302.) And whenever a repleader is granted, the pleadings must begin *de novo* at that stage of them, whether it be the plea, replication, or rejoinder, &c. in which there appears to have been the first defect, or deviation, from the regular course. Raym. 453. Salk. 579.

REPLEGIANDO *Homine, Writ de.* See Homine.

REPLEGIARE *de Averiis*, a writ brought by one whose cattle are distrained, and put in a pound, by another; upon security given the sheriff to pursue, or answer the action at law against the distrainer.

REPLETION, in the *Canon Law*, is where the revenue of a benefice or benefices is sufficient to fill or occupy the whole right or title of the graduate who holds them.

When there is a repletion, the party can demand no more by virtue of his degrees. In England, where benefices are not appropriated to degrees, repletion, strictly speaking, has no place.

In France, by the old constitution, 600 livres, or 45*l.* sterling *per annum*, made a repletion, when the benefice was obtained otherwise than by a degree; and 30*l.* *per annum*, when it was obtained by virtue of a degree.

Repletion, in *Medicine*, sometimes signifies the general fulness of the habit, which is called *plethora;* and sometimes the temporary overloading of the stomach with food and drink, which occasions particular attacks of disease, such as a fit of apoplexy, or of the gout, or a diarrhœa.

REPLEVIN, Plevina, in *Law*, a remedy granted on a distress; being a re-deliverance of the goods distrained to the first possessor, on security or pledges given by him to try the right with the distrainer, and answer him in the course of law.

If a person distrain another's goods or cattle for rent, or damage feasant, &c. the owner, upon giving security to the sheriff, that he will prosecute his action against the party distraining, and return the goods or cattle again if the seizure shall be adjudged good, may have a writ of *replevin*, or *replegiari facias*. See Distress and Replevy, *infra*.

REPLEVISH, is to let one to mainprise upon surety. See Mainprise.

REPLEVY, Replevie, (from the Latin *replegiare*, to re-deliver to the owner upon pledges of surety,) is the bringing of a writ of *replevin*, or *replegiari facias*, issuing out of chancery, by him whose cattle or goods are distrained by another upon any cause; having first given security to the sheriff, that, on the delivery of the thing distrained, he will prosecute the action against the person who made the distress.

In the stat. 24 Henry VIII. we read of *canes replegiati*, or *hounds replevied*, in a case between the abbot of St. Alban's and Geoffery Childwic.

Goods may be replevied two ways; *viz. by writ*, which is that used by the common law; and *by plaint*, which is that by statute law, for the more speedy having again the cattle and goods; and is brought in the sheriff's court.

Accordingly, the statute of Marlbridge (52 Hen. III. cap. 21.) directs, that (without suing a writ out of chancery) the sheriff, immediately upon complaint made to him, shall proceed to replevy the goods. And, for the greater ease of the parties, it is farther provided by statute 1 P. & M. cap. 12. that the sheriff shall make at least four deputies in each county, for the sole purpose of making replevins. Upon application, therefore, either to the sheriff, or one of his said deputies, security is to be given, in pursuance of the statute of Westm. 2. 13 Edw. I. cap. 2. 1. That the party replevying will pursue his action against the distreinor; for which purpose he puts in *plegios de prosequendo*, or pledges to prosecute: and, 2. That if the right be determined against him, he will return the distress again; for which purpose he is also bound to find *plegios de retorno habendo*. Besides these pledges, which are merely discretionary in the sheriff, the statute 11 Geo. II. cap. 19. requires that the officer, granting a replevin on a distress for rent, shall take a bond with two sureties, in a sum of double the value of the goods distrained; which bond shall be assigned to the avowant or person making cognizance, on request made to the sheriff; and, if forfeited, may be sued in the name of the assignee. The sheriff, on receiving such security, is immediately, by his officers, to cause the chattels taken in distress to be restored into the possession of the party distrained upon; unless the distreinor claims a property in the goods so taken. If this be the case, the party replevying must sue out a writ *de proprietate probanda*. But, if no claim of property be put in, or if (upon trial) the sheriff's inquest determines it against the distreinor, then the sheriff is to replevy the goods, if they be found within his county. When the goods are delivered back to the party replevying, he is then bound to bring the action of replevin, which may be prosecuted in the county-court; but either party may remove it to the superior courts. Blackst. Comm. book iii.

REPLICATION, Replicatio, in *Logic*, the assuming or using the same term twice in the same proposition; otherwise called *reduplication*.

Some philosophers use the phrase *replicatio mundi*, replication of the world, for its conversion, or turning round. The human soul is said to be in a place *replicatively*, *replicative*, when conceived to be all in the whole, and all in every part of it.

Replication, in *Law*, is an exception of the second degree,

gree, made by the plaintiff to the plea or firſt anſwer of the defendant.

The replication is particularly that which the plaintiff replies to the defendant's anſwer in chancery; and which is either *general* or *ſpecial*. The ſpecial is grounded upon matter ariſing out of the defendant's anſwer, &c. The general is ſo called from the general words uſed in it. See REJOINDER, and CONFESS *and avoid*.

REPLIQUE, Fr. in *Muſic*. This term, which implies an octave, has been, not very happily, rendered into Engliſh by *replicate*, in the wretched tranſlation of Rameau's treatiſe; but though it has been generally adopted, it has never ſeemed properly naturalized to our language. Sir Francis Bacon has uſed the word *recurrence* for the ſame purpoſe, which is much more congenial with our idiom. There is neceſſarily a repetition of the ſame ſound, or its octave, in every compoſition of four parts.

REPLOT, in *Geography*, one of the Quarken iſlands, in the gulf of Bothnia. N. lat. 63° 15′. E. long. 21° 7′.

REPOLON, in the *Manege*, is a demivolte, the croupe in, cloſed at five times. The Italians are extremely fond of this ſort of manege. In making a demivolte, they ride their horſes ſhort, ſo as to embrace or take in leſs ground, and do not make way enough every time of the demivolte.

REPOLOVSKOI, in *Geography*, a town of Ruſſia, in the government of Tobolſk, on the Irtiſch; 171 miles N. of Tobolſk.

REPONSE, Fr. in *Muſic*, the anſwer to a ſubject of fugue. The anſwer to a fugue, and the time when it is to be introduced, are difficulties in the art of regular fugue, concerning which young contrapuntiſts are long doubtful. See FUGUE and COUNTER-SUBJECT.

REPORT, the relation made upon oath, by officers or perſons appointed to viſit, examine, ſtate, or eſtimate any thing.

Damages, repairs, &c. are judged from the reports of experienced perſons. Proviſions for perſons wounded are only granted on the reports of ſurgeons, &c.: in caſes of rapes, a report of matrons is to be had.

REPORT, in *Law*, is a public relation, or bringing to memory, of caſes judicially argued, debated, reſolved, or adjudged, in any of the king's courts of juſtice, with the cauſe and reaſon of the ſame delivered by the judges. They are hiſtories of the ſeveral caſes, with a ſhort ſummary of the proceedings, which are preſerved at large in the record, the arguments on both ſides, and the reaſons the court gave for its judgment: taken down in ſhort notes by perſons preſent at the determination: theſe ſerve as indexes to, and alſo to explain, the records.

Theſe reports, which in matters of conſequence and nicety the judges direct to be ſearched, are extant in a regular ſeries from the reign of king Edward II. incluſive; and from his time to that of Henry VIII. were taken by the prothonotaries, or chief ſcribes of the court, at the expence of the crown, and publiſhed annually; whence they are known under the denomination of the "Year-books." And it is much to be wiſhed (ſays judge Blackſtone) that this beneficial cuſtom had, under proper regulations, been continued to this day; for though king James I., at the inſtance of lord Bacon, appointed two reporters, with a handſome ſtipend, for this purpoſe, yet that wiſe inſtitution was ſoon neglected; and from the reign of Henry VIII. to the preſent time, this taſk has been executed by many private and contemporary hands; who ſometimes through haſte and inaccuracy, ſometimes through miſtake and want of ſkill, have publiſhed very crude and imperfect (perhaps contradictory) accounts of one and the ſame determination. Some of the moſt valuable ancient reports are thoſe publiſhed by lord chief juſtice Coke, which are ſo highly eſteemed, that they are generally cited without the author's name; and are ſtiled κατ' ἐξοχὴν, *the reports*. The reports of judge Croke are alſo cited in a particular manner, by the name of thoſe princes in whoſe reigns the caſes reported in his three volumes were determined, *viz.* queen Elizabeth, king James, and Charles I., as well as by the number of each volume. Blackſt. Com. book i. &c.

When the chancery, or any other court, refers the ſtating of ſome caſe, or comparing an account, &c. to a maſter in chancery, or other referee, his certificate therein is alſo called a report.

REPORTS, in *Military Matters*, are daily, weekly, and monthly reports of the ſtate of the companies or regiments, relative to their being preſent or abſent, on duty, ſick, confined, &c.

General officers report to the commander-in-chief only. The commander-in-chief's guard reports to himſelf by one of his aid-de-camps. Reports of cavalry are given in to the ſenior generals of cavalry; and reports of infantry to the ſenior general officers of infantry. On a march the field officer of the piquet reports to the general of the day who leads the column; and in camp to the next ſuperior officer to himſelf. A provoſt martial gives in his return of priſoners, and reports to the general of the day.

Deputy judge advocates, acting in diſtricts or garriſons, &c. ſend in the minutes of courts martial, and report to the judge advocate general, without going through any general officers. Regimental ſurgeons report to their commanding officers, and ſurgeons in diſtricts, &c. to the medical board.

The life-guards report, through the Gold Stick, to the king direct, from whom they receive the parole.

The foot-guards report, through the field officer of the day, to the king direct.

All other troops belonging to the Britiſh ſervice, the marines excepted, who report to the admiralty, report through their ſeveral commanding officers, &c. to the adjutant-general and ſecretary at war, and to the commander-in-chief.

A *ſpecial* report is ſaid to be made when the name of an officer is tranſmitted by his commander to the general of a diſtrict, independent of the regular returns; and ſome ſpecific inſtance of miſconduct is laid before him. It muſt be generally remembered, that every officer, on his arrival from abroad with a regiment or detachment of troops, muſt report himſelf to the governor or commanding officer of the ſeaport at which he arrives; and every officer who takes his paſſage for foreign ſervice, muſt do the ſame previous to his departure.

The ſenior officer in each recruiting quarter reports weekly to the field officer of the diſtrict, the number and ſtrength of the parties therein. The field officers commanding recruiting parties in diſtricts, report to the inſpector-general, to whom all returns and reports are to be tranſmitted by them, and not direct from the recruiting officers.

The various ſubordinate reports are thoſe of a rear-guard, of a barrack-guard, of a quarter-guard, of a main-guard and its dependencies, &c. &c.

In the column of remarks which muſt accompany each of theſe reports, it is neceſſary, for the perſon who ſigns, to ſpecify all caſualties and extraordinary occurrences according to the particular nature of each report. The different hours at which the grand rounds, viſiting rounds, and patroles went, muſt likewiſe be put down.

REPORT, *Pinion of*. See PINION.

REPOS, Fr. in *Muſic*, a repoſe, or pauſe. It is the termi-

termination of a phrafe or period. The repofe here meant refembles a hyatus in verfification ; it is a cadence more or lefs perfect as the bafe falls a third, a fifth, or rifes to the fixth of the key. It is a kind of refting place, determined by the fenfe of the paffage, and by feeling. See CADENCE and CADENZA.

REPOSE, in *Poetry*, &c. See REST, PAUSE, &c.

REPOSE, in *Painting*, is applied to certain maffes, or large fyftems of affemblages of light and fhade ; which, being well conducted, prevent the confufion of objects and figures ; by engaging and taking up the eye fo as it cannot attend to the other parts of the painting for fome time ; and thus leading it to confider the feveral groupes gradually, and, as it were, to proceed from ftage to ftage.

REPOSE, *In*, in *Military Language*, is a phrafe that applies to troops which are allowed to be ftationary for any given period, during an active campaign, either through ficknefs, or from fome other caufe.

REPOSITION *of the Foreft* (formed from *re*, and *ponere to lay again*), an act by which certain grounds, before made purlieu, are, upon a fecond view, laid to the foreft again.

REPOSITION, in *Surgery*, the reduction of a bone.

REPOSITORY, REPOSITORIUM, a ftore-houfe or place where things are laid up and kept. In which fenfe we fay, the repofitory of the royal fociety, the royal repofitory at Woolwich, containing models of every fort of warlike ftores, &c. See MUSEUM.

REPOSITORY *of Farm Manure*, in *Rural Economy*, the place where it is put or laid up. See RECEPTACLE *of Stall Manure*.

REPOSO, in *Geography*, a fmall ifland near the coaft of Brafil ; S. lat. 19° 36′.

REPPELE, a town of Hinder Pomerania ; 7 miles W.S.W. of Zachau.

REPPIN, a town of Brandenburg, in the New Mark, on the Eylang ; fix miles S.S.W. of Droffen, N. lat. 52° 25′. E. long. 15° 2′.

REPREHENSION, in *Rhetoric*. See PARRHESIA.

REPRESENTATION, REPRÆSENTATIO, in the *Drama*, the exhibition of a theatrical piece ; including the fcenes, machines, recitation, &c.

Sir Richard Steele's principle is, that the defign of a play is not to be read but reprefented ; fo that it is on the ftage, not in the prefs, it is to be judged of ; and that the pit, not the public, are the proper judges.

REPRESENTATION, in *Law*. See DESCENT, *Right of* CROWN, INTESTATE, ADMINISTRATION, and PARLIAMENT.

REPRESENTATION, in *Infurance*, is underftood to mean a collateral ftatement, either by parol or in writing, of fuch facts or circumftances relating to the propofed adventure, and not inferted in the policy, as are neceffary for the information of the infurer, to enable him to form a juft eftimate of the rifk. Such reprefentations are often the principal inducement to the contract, and afford the beft ground upon which the premium can be calculated. A reprefentation may be untrue, either wilfully and fraudulently ; or inadvertently and innocently.

A wilful mifreprefentation, or *allegatio falfi*, in any fact or circumftance *material to the rifk*, is a fraud that will always avoid the contract. As if an agent, knowing that a fhip had failed from Jamaica for London on the 24th of November, effect an infurance on the voyage, and tell the underwriter that the fhip failed in December : this is a fraud, and the policy is void.

And fuch mifreprefentation fo completely vitiates the policy, that the infured cannot recover upon it, even for a lofs arifing from a caufe unconnected with the fact or circumftance mifreprefented. As if the infured reprefent that the fhip or goods infured are neutral property, when in fact they are enemy's property ; he fhall not recover even for a lofs occafioned by fhipwreck.

So it would be if the broker or agent were to affert that a fhip or goods were neutral property, without knowing whether this were true or falfe, and they are, in fact, enemy's property : for, though it may not, perhaps, be equally criminal *in foro confcientiæ* for a man to aver that to be true which he knows nothing of, as to aver that to be true which he knows to be falfe ; ftill it is unqueftionably a fraud, and in the cafe of an infurance, equally injurious to the underwriter ; becaufe he is induced by the deception, however occafioned, to compute the rifk upon falfe principles. The fame reafoning holds even in the cafe where the perfon himfelf making the reprefentation *believes* it to be true.

But if he were only to fay that he *believes* the fhip to be neutral property, knowing nothing on the fubject, and having no reafon to believe the contrary ; there, though the fhip be not neutral, the reprefentation will not avoid the policy ; becaufe the under-writer may inform himfelf of the grounds of this belief, before he enters into the contract ; and if he neglect to do fo, he takes upon himfelf the rifk of its being unfounded.

For the fame reafon, if the word *expected* be ufed, this will not amount to a reprefentation : as when a broker in getting infurances effected on feveral fhips, belonging to the fame owner, and fpeaking of them all, faid,—'Which veffels are *expected* to leave the coaft of Africa in November or December,' when, in fact, they had all failed in the May preceding : this does not amount to a reprefentation, being only an *expectation*, the ground of which the under-writer might have enquired into.

There is a material difference between a reprefentation and a warranty. A warranty, being a condition upon which the contract is to take effect, is always a part of the written policy, and muft appear on the face of it : whereas a reprefentation is only matter of collateral information or intelligence on the fubject of the voyage infured, and makes no part of the policy. A warranty, being in nature of a condition precedent, muft be *ftrictly and literally* complied with; but it is fufficient if a reprefentation be true in *fubftance*. By a warranty, whether material to the rifk or not, the infured ftakes his claim of indemnity upon the precife truth of it, if it be affirmative, or upon the exact performance of it, if executory ; but it is fufficient if a reprefentation be made without fraud, and be not falfe in any material point ; or if it be *fubftantially*, though not *literally*, fulfilled. A falfe warranty avoids the policy, as being a breach of a condition upon which the contract is to take effect, and the infurer is not liable for any lofs though it do not happen in confequence of the breach of the warranty. A falfe reprefentation is no breach of the contract, but if material, avoids the policy on the ground of *fraud*, or at leaft becaufe the infurer has been mifled by it.

It has already been fhewn that a warranty muft appear upon the face of the policy, and make a part of the written contract ; and therefore a written paper, wrapped up in the policy, or even wafered to it, is only a reprefentation. For the fame reafon, the written inftructions for effecting the policy, unlefs inferted in it, cannot be deemed a warranty, but only a reprefentation ; for the under-writer, by not infifting on having thefe inftructions inferted in the policy, fhews that he is content to take them as a reprefentation.

But

but it behoves all agents and brokers concerned in the effecting of policies, to keep correct entries of theſe inſtructions, and indeed of all repreſentations made to the under-writers: for the whole queſtion between the inſured and the under-writers often turns upon theſe inſtructions. Beſides, they are anſwerable to the inſured for the conſequences of any repreſentation made by them without authority, as well as for thoſe of omitting to make ſuch repreſentations as they have been inſtructed to make.

By an extenſion of equitable relief in caſes of fraud, it ſeems to be now ſettled that if a falſe repreſentation be made to the firſt under-writer on the policy, in a material point, this ſhall be conſidered as a miſrepreſentation made to every under-writer, ſo as to infect the whole policy, otherwiſe it might be a contrivance to deceive many; for when a reſpectable under-writer ſtands firſt on the policy, the reſt ſubſcribe the policy without aſking a queſtion; and if the firſt under-writer be impoſed upon, the reſt are entrapped by the ſame fraud.

But the inſurer muſt avail himſelf of this ſort of objection in the firſt inſtance; for after a verdict has been obtained, the court will not ſet it aſide upon an affidavit of the firſt under-writer, that a material miſrepreſentation had been made to him. The defendant, in ſuch caſe, knows what has been repreſented to himſelf, and might have known what had been repreſented to the firſt under-writer; and he ſhall not lie by till after a trial, in order to make the objection, if the verdict ſhould be againſt him.

If the inſured ſtate his computation as *fact*, inſtead of the information on which he founds his computation, and it prove untrue, it is a miſrepreſentation; and if material, it will avoid the policy.

A miſrepreſentation in a material point equally vitiates the contract, whether it be the miſrepreſentation of the inſured himſelf or of his agent, and whether it proceed from fraud, miſtake or negligence; for the inſurer is thereby led into an error, and computes the riſk upon falſe grounds.

As a repreſentation is only matter of collateral information, it is ſufficient if it be true in *ſubſtance;* and its not being inſerted in the policy in the form of a warranty, is looked upon as a proof that the inſurer does not require it to be ſtrictly and literally true. Although the voyage be repreſented as being leſs than the voyage deſcribed in the policy, yet, if there be no fraud, and the voyage actually performed be within the policy, it will be protected by the policy. Even if a repreſentation as to the courſe of the voyage be literally untrue, yet if it be made in conformity to an eſtabliſhed uſage of trade, and no perſon be deceived by it, and the voyage meant to be performed be within the policy, it will not avoid the contract.

Every repreſentation reſpecting the ſtate of the ſhip, and the time of her ſailing, is material; and therefore if it be ſtated that a ſhip was *ready to ſail* on a certain day, when, in fact, ſhe had ſailed the day before, this is both a miſrepreſentation and a concealment, and will avoid the policy.

Concealment, or "ſuppreſſio veri," is nearly allied to miſrepreſentation, or "allegatio falſi," and conſiſts in the fraudulent ſuppreſſion of any fact or circumſtance material to the riſk; and this, like every other fraud, avoids the contract *ab initio,* upon principles of natural juſtice. But it is not merely on the ground of *fraud* that a concealment avoids the contract; for even a concealment which is only the effect of accident, negligence, inadvertence, or miſtake, will be equally fatal to the contract, as if it were intentional and fraudulent. Whatever reſpects the ſtate of the ſhip, the time of her ſailing, the nature of the employ in which ſhe is to be engaged, &c. ought to be fully diſcloſed; and the keeping back of any part of this fact will be fatal to the contract. In ſuch caſe, the concealment ſo vitiates the policy that it will afford the inſured no remedy, even for a loſs ariſing from a cauſe unconnected with the fact or circumſtance concealed; for a concealment is to be conſidered, not with reference to the event but to its effect, at the time of making the contract. A well-founded ſuſpicion of concealment will amount in the courts to proof of fraud. As it is in ſome caſes neceſſary to ſtate to the under-writers the nature of the ſervice in which the ſhip is to be employed; if this be attended with any extraordinary danger, the concealment of it will avoid the policy. A material concealment is fatal, though the fact concealed was not diſcloſed, becauſe the broker thought it immaterial. Doubtful rumours reſpecting the ſafety of a ſhip which it is intended to inſure "loſt or not loſt," ought to be faithfully diſcloſed to every under-writer; and the withholding of ſuch information will avoid the contract. The obligation of a ſtrict obſervance of good faith is equally binding on both parties in all contracts; and in that of inſurance, the under-writer, as well as the inſured, is bound to diſcloſe all circumſtances within his knowledge affecting the riſk. If, therefore, it ſhould appear, that at the time when he underwrote the policy, he knew that the ſhip was arrived ſafe, the contract will be void as to him, and an action will lie againſt him to recover back the premium.

There are, however, many matters, which are open to both parties, and upon which they may both exerciſe their judgments, with regard to which they may be innocently ſilent. The inſured need not diſcloſe what the under-writer knows, or what he ought to know. The under-writer needs not be told what leſſens the riſk agreed upon, and is underſtood to be compriſed within the terms of the policy. He is bound to know every cauſe which may occaſion natural perils, as the difficulty of the voyage, the variation of ſeaſons, the probability of lightning, hurricanes, &c. He is alſo bound to know every cauſe which may occaſion political perils, from the rupture of ſtates, from war, and its various operations; and he is bound to know the probability of ſafety from the continuance and return of peace, from the imbecility of the enemy, the weakneſs of their counſels, or their want of ſtrength. There are other circumſtances which the under-writer ought to know; and, particularly, it is not neceſſary to communicate to him, that the ſhip is foreign built, though this enabled her to ſail without convoy, and without a licence to do ſo, being within the exception in the ſtat. 38 Geo. III. c. 76. § 6; it being the buſineſs of the under-writer to obtain this information for himſelf. In caſes of concealment, the queſtion muſt always be, whether there was, under all the circumſtances, at the time when the policy was underwritten, a full and fair ſtatement, or a concealment: fraudulent, if deſigned; or, though not deſigned, varying materially the object of the policy, and changing the riſk underſtood to be run; and in both caſes avoiding the contract. It is not neceſſary that there ſhould be any previous repreſentation as to the ſtate of the ſhip, that being covered by the implied warranty that ſhe is ſea-worthy. For a variety of other particular facts and documents, relating to the ſubjects of repreſentation and concealment, we refer to Marſhall's Treatiſe on the Law of Inſurance, vol. i. b. 1. ch. 9 and 10. See WARRANTY.

REPRESENTATIVE, one that perſonates, or ſupplies the place of another; and is inveſted with his right and authority.

The word repreſentative is equivalent to procurator or proxy.

The

The commons are the people's reprefentatives in *parliament;* which fee.

There is this defect in the conftitution of our parliament; that whereas all Englifhmen who have confiderable eftates ought not to be taxed without their own confent in parliament, by themfelves, or their reprefentatives; copyholders, of whom fome have a thoufand pounds a-year, have no voice in the election of knights of the fhire. See PARLIAMENT.

REPRESENTATIVE *Character*, in *Political Economy*, thus denominated by way of excellence, or in contradiftinction to other kinds of reprefentation, conftitutes the ambaffador, or minifter of the firft rank, who reprefents his mafter in his very perfon and dignity. It places him above all other minifters, who are not invefted with the fame character, and precludes their entering into competition with the ambaffador. (See EMBASSADOR.) Envoys are minifters of the fecond rank, and are not invefted with the reprefentative character, properly fo called, or in the firft degree. See ENVOY.

REPRESENTATIVE *Power*, in *Metaphyfics*, a term introduced by Leibnitz, to fignify that power of the human foul, by which it reprefents to itfelf the univerfe, according to the fituation of the body in the univerfe.

Wolfius calls this power *vis reprefentativa*, to denote its being an active power, or rather a force actually exerting itfelf. For he exprefsly fays, *quod vis confiftat in continuo agendi conatu*. And he thinks that from this principle of a *vis reprefentativa*, every phenomenon of the human mind may be accounted for. See his Pfycholog. Ration. art. 529.

But it may be prefumed, that many will find this principle too obfcure to be admitted.

When it is faid, that our ideas are reprefentative of things without us, or of the univerfe; it may be afked in what fenfe this is to be underftood? Do they reprefent it, 1. As a picture does its original? Or, 2. As an effect of a caufe? Or, 3. As a fign reprefents the thing fignified? The firft opinion is exploded in part by Locke and the Cartefians, and totally by Dr. Berkeley, late bifhop of Cloyne. The fecond is admitted by Hobbes, but denied by Leibnitz himfelf and the idealifts. The third fhould feem to be the opinion of Leibnitz, but he is not fufficiently explicit.

Dr. Berkeley admits ideas to be figns; but according to him they are arbitrary figns, depending on the immediate will of the Deity: hence the vifual language; and ideas only fignify or fuggeft each other, and fpirits; but not bodies, the exiftence of which is totally unknown.

REPRIEVE, or REPRIVE, from *reprendre, to take back*, in *Law*, a fufpending or deferring the execution of the law upon the prifoner for the prefent time.

A reprieve is properly a warrant from the king, for fufpending the execution of a perfon condemned.

This may be, firft, *ex arbitrio judicis*, either before or after judgment; as, where the judge is not fatisfied with the verdict, or the evidence is fufpicious, or the indictment infufficient, or he is doubtful, whether the offence be within clergy; or fometimes, if it be a fmall felony, or any favourable circumftances appear in the criminal's character, in order to give room to apply to the crown for either an abfolute or conditional pardon. Thefe arbitrary reprieves may be granted or taken off by the juftices of gaol-delivery, although their feffion be finifhed, and their commiffion expired; but this rather by common ufage than by ftrict right. (2 Hal. P. C. 412.) Reprieves may alfo be *ex neceffitate legis*, as where a woman is capitally convicted, and pleads her pregnancy; which is referred to a *jury of matrons*. Another caufe of regular reprieve is, if the offender become *non compos* between the judgment and the award of execution. See LUNATIC.

REPRIMAND, a fharp authoritative reproof. Such a perfon was reprimanded in court by the bench, &c.

REPRIMAND, a military punifhment at the head of a regiment, is fometimes ordered by a court-martial, and fometimes only in the prefence of the officers of the corps: it is generally given by one of the field-officers, and ufually in fuch terms as thefe: "Captain, or lieutenant A. B., you have been tried for ——, and are, by the fentence of a general court-martial, found guilty thereof, and fentenced to be reprimanded at the head of the regiment: the difagreeable tafk of doing it is affigned to me: I therefore do hereby reprimand you, and hope, that it may prevent your falling again into the like error." Non-commiffion officers are fometimes, though not frequently, ordered to be reprimanded.

REPRISALS, or REPRIZALS, *Reprifalia*, in the *Civil Law*, a right which princes have to retake from their enemies fuch things as they unjuftly detain from them; or other things equivalent to them.

The word is formed from the Italian *reprefaglia*, which fignifies the fame thing.

When a place is taken or held from a prince, he feizes another by way of reprifal. Sometimes he takes men of the oppofite party, by right of reprifals.

The Romans called this *clarigatio;* and the Greeks had fomething like it under the name of *androlepfia*.

Reprifals are ufed between nation and nation, to do juftice to themfelves, when they cannot otherwife obtain it. If a nation has taken poffeffion of what belongs to another; if it refufes to pay a debt, to repair an injury, or to make a juft fatisfaction; the other may feize what belongs to it, and apply it to its own advantage, till it has obtained what is due for intereft and damage, or keep it as a pledge till full fatisfaction has been made. The law of nations permits reprifals only upon a caufe that is evidently juft, as for a debt that is extremely clear. For he who forms a doubtful pretenfion, can at firft demand only an equitable examination of his right. In the fecond place, he fhould, before he proceeds fo far, have in vain demanded juftice, or, at leaft, have the utmoft reafon to believe that it would be in vain for him to demand it. Then alone he may right himfelf. It would be too contrary to the peace, to the repofe, and fafety of nations, to their mutual commerce, and to the duties which bind them to each other, for any prince fuddenly to apply to force, without knowing whether the other is difpofed to do him juftice, or to refufe it. It muft be obferved, in order perfectly to underftand this article, that if, in a litigious affair, our adverfary refufes the means of bringing the right to proof, or artfully eludes it; if he does not, with good faith, apply to pacific meafures for terminating the difference; and, above all, if he is the firft who begins acts of hoftility, he renders the caufe juft, which was before doubtful: we may then make ufe of reprifals, or feize his effects, to oblige him to embrace the methods of reconciliation, which the law of nature prefcribes. This is the laft attempt before coming to an open war. As the wealth of the citizens forms a part of the total wealth of a nation, and between ftate and ftate, whatever is the property of the members is confidered as belonging to the body, and is anfwerable for the debts of the body; it follows, that in reprifals they feize the goods of the fubject, in the fame manner as thofe of the ftate, or fovereign. Every thing that belongs to the nation is fubject to reprifals, as foon as it can be feized, provided it be not a depofit trufted to the public faith. This depofit is found in our hands, only

only in consequence of that confidence which the proprietor has put in our good faith; and it ought to be respected, even in cases of open war. Thus it has been usual to behave in France, England, and elsewhere, with respect to the money which foreigners have placed in the public funds. He, however, who makes use of reprisals against a nation, on the goods of its members indiscriminately, cannot be taxed with seizing the wealth of an innocent person for the debt of another; for, in this case, the sovereign is to recompense those of his subjects on whom the reprisals fall: this is a debt of the state or nation, of which each citizen ought only to support his quota. It belongs only to sovereigns to use and order reprisals, in the manner now stated. This is a measure of too great consequence to be abandoned to private persons. In all civilized states, a subject who thinks himself injured by a foreign nation has recourse to his sovereign, in order to obtain the permission of making reprisals. This is what is called desiring "letters of marque." See the next article.

We may use reprisals against a nation, not only for the actions of the sovereign, but also for those of his subjects. Accordingly the sovereign demands justice, or makes reprisals, not only for his own affairs, but also for those of his subjects, whom he ought to protect, and whose cause is that of the nation. But to grant reprisals against a nation, in favour of foreigners, is to set himself up as a judge between that nation and these foreigners, which no sovereign has a right to do.

As we may seize the things which belong to a nation, to oblige it to do justice, we may, for the same reason, arrest some of the citizens, and not release them till we have received entire satisfaction; the subjects thus detained being only regarded as a security to oblige a nation to do justice, if their sovereign is obstinate in refusing it. We cannot take away their lives, nor inflict any corporal pain upon them, for a refusal of which they are not guilty. But the sovereign may make use of force against those who resist the execution of this right, and use as much as is necessary to surmount their unjust resistance. In this case, the true and just welfare of the state is the grand rule: moderation is always laudable in itself; but the conductors of nations ought to exercise it only so far as it is consistent with the happiness and safety of their people. A sovereign, however, has no right to oppose force, or to make war against him, who, in such a case, by ordering the making of reprisals, only exercises his just right. Whenever a sovereign can, by the way of reprisals, procure a just recompence, or a proper satisfaction, he ought to make use of this method, which is less violent and less fatal than war. Those who run to arms, says the excellent Vattel, without necessity, are the scourges of the human race, barbarians, enemies to society, and rebels to the law of nature, or rather to the common father of mankind. There are cases, however, in which reprisals would be justly condemned, even when a declaration of war would not be so; and these are precisely those in which nations may with justice take up arms. When it relates to differences, not on an act of violence, or of an injury received, but of a contested right; after having in vain attempted ways of reconciliation, or pacific measures of obtaining justice, it is a declaration of war which ought to follow, and not pretended reprisals, which, in such a case, would only be real acts of hostility, without a declaration of war, and would be contrary to the public faith as well as to the mutual duties of nations.

There is one kind of retortion sometimes practised in war, under the name of reprisals, which we must here mention. If a general of the enemy has, without any just reason, caused some prisoners to be hanged, a like number of his men, and of the same rank, will be hung up; signifying to him, that this retaliation will be continued for obliging him to observe the laws of war. It is a sad extremity thus to put a prisoner to death for his general's fault; and if this prisoner was before promised his life, reprisals cannot be made on him with any colour of justice. Yet as a prince, or his general, has a right of sacrificing the life of his enemies to his safety, and that of his men, if he is engaged with an inhuman enemy, who frequently commits such enormities, he appears to have a right of refusing life to some of the prisoners he may take, and of treating them as his were treated. But Scipio's generosity is rather to be imitated. That great man, having reduced some Spanish princes, who had revolted against the Romans, declared to them, that on a breach of their faith, he would not call the innocent hostages to an account, but themselves; and that he would not revenge it on a disarmed enemy, but on those who should be found in arms. (Liv. l. 28.) Alexander the Great, having cause of complaint against Darius for some malpractices, sent him word, that if he continued to make war in such a manner, he would pursue him to the utmost, and give no quarter. (Quint. Curt. l. iv. c. 1, and 11.) It is thus an enemy, violating the laws of war, is to be punished, and not by causing the penalty due to his crimes to fall on innocent victims. Vattel's Law of Nations, b. ii. ch. 18. b. iii. ch. 8.

Reprisals is also used for a letter or permission, which a prince sometimes gives a subject, upon a full cognizance of the cause; authorizing him to retake from the first persons he meets of the opposite party, as many effects as make an equivalent to what have been violently forced from him, and for which the opposite prince has refused to do him justice.

These permissions are also called *letters of marque*, or *mart;* and in the stat. 27 Edw. III. *law of marque;* in regard a person denied justice in another man's territory, redresses himself by goods belonging to men of that territory. See *Letters of* Marque.

Reprisals is also used in the same sense with recaption.

REPRISE, or Reprize, in the *Commerce by Sea*, a merchant-ship, which, having been taken by a corsair, privateer, or other enemy, is retaken or recovered by a vessel of the contrary party.

The word is French, and signifies a *resumption* or *retaking*.

When a vessel, thus retaken, has been twenty-four hours in the hands of the enemy, it is deemed a lawful prize. If the reprize has been made within twenty-four hours, the vessel is to be restored to the proprietor, with every thing in it, upon his allowing one-third to the vessel who made the reprize.

If the reprize has been abandoned by the enemy, either in a tempest, or from any other cause, before it have been led into any port, it is to be restored to the proprietor. See Recapture.

Reprise, in the *Manege*, is a lesson repeated, or a manege recommenced. Thus we say, to give breath to a horse upon the four corners of the volte with only one reprise, that is, all with one breath.

Reprise, Fr., in *Music*. Every part of an air or strain that is to be repeated, without being written or printed twice over, is called by the French a reprise. There are various ways of marking repetitions in music: first by a double bar dotted; if on both sides, both parts or strains are

are to be repeated; if only one ſide of the double bar is dotted, that ſide only is to be repeated. This ſign 𝄋, and ſometimes *da capo al ſegno* 𝄋, imply a repetition of particular portions of a melody; as do, likewiſe, dots in the ſpaces of the ſtaff. (See Renvoi and Reference.) Gretry, in his Memoires, ſays that the repeating of the firſt and ſecond parts or ſtrains of a movement is a barbarous cuſtom.

Reprises, in *Law*, are deductions, drawbacks, or duties, paid yearly out of a manor, or lands. Such are rent-charges, penſions, fees of ſtewards or bailiffs, &c. The manor of Doll yields 40*l. per annum, ultra reprizas*, beſides all reprizes.

REPROBATION, Reprobatio, in *Theology*, a decree or reſolve, which God has taken from all eternity to puniſh ſinners, who ſhall die in impenitence.

Reprobation ſtands in direct oppoſition to *election.*

Divines hold it a ſymptom of reprobation, when a ſinner is hardened ſo as not to feel any farther remorſe or miſgivings of conſcience.

The caſuiſts diſtinguiſh two kinds of reprobation, *poſitive* and *negative*. *Poſitive* is that by which God is ſuppoſed to create men with a poſitive and abſolute reſolution to damn them eternally. This opinion of reprobation is countenanced by St. Auguſtine, and others of the fathers; and is ſtrongly maintained by Calvin, and moſt of his followers. Something like it is alſo found in the thirty-nine articles of the church of England; but it is now generally exploded, as injurious to the juſtice of God. *Negative* or *conditional* reprobation is that by which God, though he creates all men with a ſincere deſire to ſave them, and furniſhes them with the neceſſary means thereto, ſo that all may be ſaved, if they will; yet ſees there are ſeveral who will not do it, with the aids he ſhall afford them, how powerful ſoever; and ſees, at the ſame time, they would do it with certain other aids, which he ſees, but will not give them. *O altitudo!* &c.

By comparing one part of ſcripture with the other, ſays Dr. Doddridge in his "Lectures," (Prop. 142, ſchol. 1.) there ſeems to be this remarkable difference between the predeſtination to life and that to death (here called reprobation), that, in the former caſe, God determines by the influence of his grace to work ſuch a change in the hearts of his elect, as that their ſalvation ſhould on the whole be aſcribed to him, and not unto themſelves; whereas he determines to bring others into ſuch circumſtances, that though their ruin ſhould in fact happen, yet they themſelves ſhould be the authors of it, and the blame lie as entirely upon themſelves, as if it had not been ſo much as foreknown. (See Rom. ix. 22, 23. Matth. xxv. 34, 41.) But the oppoſers of this doctrine allege, that this kind of reaſoning is an evaſion and not a ſolution of the difficulty. This learned divine, adverting to the objection, that the above-ſtated doctrine tends to make the perſons whom it concerns deſperate, obſerves, that if it be granted, that *ſufficient* aſſiſtances are given to *all*, none will have reaſon to deſpair, nor will any have an excuſe to plead before God, in conſequence of his ſecret purpoſes, which will not be made a rule of his final judgment. If it be ſaid, that nevertheleſs thoſe who are not predeſtinated to life are left under a neceſſity of periſhing, and an impoſſibility of ſalvation; it muſt be owned, that it is difficult to ſay, how the doctrine, as explained by ſome, can be freed from this objection; but that this conſequence does not neceſſarily follow from it, according to his ſtatement. See Election and Predestination. See alſo Sublapsarian and Supralapsarian.

REPRODUCTION, in *Phyſiology*. In ſpeaking of the growth of organic bodies, we muſt notice their power of reproduction; that wonderful property of reſtoring or renewing parts that have been mutilated or entirely loſt. This is one of the moſt important proviſions of nature, inaſmuch as it guards animals and plants againſt the multiplied dangers to which their bodies are expoſed. Hence, when viewed in connection with the ſyſtem of nutrition altogether, it forms one of thoſe deciſive and grand characters, which diſtinguiſh at once the machines that proceed from the hand of the Creator, from all, even the moſt ingenious and boaſted, productions of human ſkill. The difference is recogniſed at the firſt glance; the diſtance is immeaſurable. The ſprings and wheels of mechanical inſtruments have no power of repairing themſelves, when they are bent, broken, worn, or ſpoiled; but ſuch a faculty is enjoyed in various degrees by every animal and by every plant.

At different periods of the year, ſeveral organiſed beings loſe, by a ſpontaneous and natural proceſs, certain parts of their body, which are ſubſequently renewed. Examples of this occur in the fall of the ſtag's horns; in the moulting of birds; in the renewal of the cuticle of ſerpents, and other amphibia, of the larvæ of inſects, and of the ſhell of the cruſtacea; the fall of the leaves of trees, &c. This may be called ordinary or natural reproduction. The ſtag's horn, or antler, as it ſhould be more properly called, is a maſs of true bone, poſſeſſing the ſtructure and characters of oſſeous ſubſtances. In its early ſtate, it is ſoft, and traverſed by large veſſels, which muſt be reproduced every time the new horn is formed. This annual reproduction conſtitutes, in many points of view, one of the moſt remarkable phenomena of animal phyſiology. It affords a moſt ſtriking proof, 1ſt, of the power of the nutritive proceſs, and of the rapid growth, which is dependant on this in warm-blooded animals. For the horn of a ſtag, which may weigh a quarter of a hundred, is completely formed in ten weeks. 2dly. Of a limited duration of life in a part of an animal, entirely independent on the life of the whole animal, which in the ſtag extends to about thirty years. 3dly. Of change of calibre in particular veſſels. For the branches of the external carotid, which ſupply the horn, are ſurpriſingly dilated during its growth; and recover their former area, when that proceſs has ceaſed. 4thly. Of a peculiar ſympathy, which is manifeſted between the growth of the horns, and the generative functions. For caſtration, or any eſſential injury of the organs of generation, impedes the growth, alters the form, or interrupts the renewal of the horns. See the articles Cervus, and Horn, in *Comparative Anatomy*.

The cuticle of the ſnake is ſeparated every year, and comes off as a complete ſheath, excepting the aperture, through which the animal eſcapes: the covering of the cornea is ſhed with the reſt of the external integument.

Cruſtaceous animals (the crab, lobſter, &c.) have a ſkeleton, which ſurrounds and contains their ſoft parts, and which ſerves, at the ſame time, the purpoſes of a ſkin. When it has attained its perfect conſiſtence, it grows no more; but, as the ſoft parts ſtill increaſe, the ſhell ſeparates, and is detached, being ſucceeded by a larger one. The calcareous bodies in the ſtomachs of theſe animals, performing the office of teeth, are ſhed with the ſhell. See the article Cancer, in the account of the ſpecies *ruricola*, and *gammarus*.

The larvæ of inſects caſt their cuticular covering ſeveral times before their transformation. An intereſting account of the

the particulars may be feen in the article ENTOMOLOGY, in the divifion "*of the larva ftate,*" under the fubdivifion "*lepidoptera.*"

The fecond, or *extraordinary* kind of reproductive power, is that by which wounds, fractures, or any accidental mutilation or lofs of parts of an organifed body, are remedied or reftored. This exifts in very different degrees in different departments of the animal kingdom. In man, and fuch animals as are nearly allied to him, the property is very limited, although fufficiently active to be capable of remedying the effects of great injuries. If a bone be broken, a mufcle or tendon divided, or a piece of fkin deftroyed, proceffes are fet up in the parts by which reftoration is accomplifhed. The ends of the bone are joined by an offeous fubftance, which gives to the part its original folidity; the tendon regains its firmnefs and power of refiftance; the mufcle can contract again and move the points of its attachment; and the furface of the body is covered by a new piece of integument. The functions of the parts are reftored; but the newly formed matter can be always diftinguifhed from the original compofition of the body, and poffeffes a weaker vitality. For, in fome cafes, old ulcers have broken out afrefh, and even fractures have been difunited in ftates of great general debility. A divided nerve is reunited, even if a fmall portion be removed: and the function of the part, fufpended for a time, is thus reftored. The cafe is different in the blood-veffels: the proceffes confequent on wounds of thefe tend to ftop the hemorrhage, which in general can be effected only by the obliteration of the tube.

The power of repairing the effects of injury is modified by various circumftances. The health and ftrength of the individual, the age, the air, and other circumftances, which the furgeon muft attend to, have great influence.

In the cafes which have been juft mentioned, the reftorative power repairs injuries; but it goes no further. Neither in man, nor in any warm-blooded animals, are entire organs ever reproduced. If a limb be cut off, or a piece of flefh taken away, the wound is healed, the chafm is filled up; but the loft parts are never formed again.

In the lower orders of the animal kingdom, on the contrary, fuch are the ftrength and perfection of the reproductive energy, that confiderable members are formed again, and we can hardly affign a limit to the power in fome inftances. The lower we defcend in the fcale of beings, the more furprifing are the manifeftations of this reproductive faculty. It is familiarly known, that the claws of the crab and lobfter, and the entire limbs or tail of the newt, can be reftored: the fame holds good of the rays of the ftar-fifh (afterias), and the arms or tentacula of the cuttlefifh. It was afferted by Bonnet and Spallanzani, that the entire head of the fnail can be reproduced; but the affertion was fufpected, becaufe other experimentalifts did not fucceed in repeating the trials. Hence Blumenbach was led to obferve, "that fome experiments on this reproductive power require a hand exercifed in fuch employments, together with various precautions, and a favourable combination of circumftances, for their fuccefs. Hence perfons muft be cautious in concluding againft the truth of any ftatement, becaufe their own experiments do not fucceed. After feveral fruitlefs attempts on this fubject, I have lately fucceeded in obferving the reproduction of the whole head of the fnail (helix pomatia) with its four horns, which occupied about fix months." Comparative Anatomy, tranflated by Lawrence, p. 219.

The fame phyfiologift has given us a remarkable inftance of reproduction in an animal of more complicated ftructure. "I preferve," fays he, "in fpirits a large water newt (lacerta paluftris), from which I extirpated nearly the whole eye feveral years ago: all the humours were difcharged, and then four-fifths of the emptied coats were cut away. In the courfe of ten months an entirely new eye-ball was formed, with cornea, iris, cryftalline lens, &c.; and this is only diftinguifhed from the fame organ on the oppofite fide by being fmaller." Ibid.

Not only are amputated tentacula fpeedily replaced in the actiniæ (fea anemones), but, if the animal be divided by a vertical or horizontal fection into two halves, each of thefe becomes an entire actinia. See the article ANEMONE.

The frefh water polype exhibits very furprifing powers in this way. If it be cut into two or more pieces, thefe become perfect animals. If it be flit half way down, the two halves are rendered perfect, remaining united below: thefe may be flit again with the fame refults. The oppofite ends of two polypes may be made to grow together, &c. See POLYPE.

See the memoirs on animal re-productions in Spallanzani's tracts: alfo the works of Bonnet.

REPROOF, OBJURGATIO, in *Rhetoric*, is diftinguifhed from *invective*; which fee.

REPS, in *Geography*, a town of Tranfilvania; 16 miles N. of Fogaras.

REP-SILVER, money anciently paid by fervile tenants to their lord, to be quit of the duty of reaping his corn.

REPTILES, in *Comparative Anatomy* and *Phyfiology*. Although the animals, whofe ftructure we are about to explain, are perfectly fimilar to each other in their principal characters, and ought therefore to be united in one clafs, naturalifts have experienced a real difficulty in difcovering an appropriate name for the clafs. That of *amphibia*, employed by Linnæus and his difciples, although deduced from a ftriking circumftance in the economy of the more generally known reptiles, namely, the power of exifting for a long time in water, as well as in air, is vague and uncertain in its fignification. If we regard as amphibia thofe aquatic animals, which are able to live for fome time on land, or thofe land animals, which can remain for a certain time under water, all animals are amphibious; for even the human fubject and the mammalia can dive. If, on the other hand, the word amphibious be taken etymologically, and underftood to denote an equal power of fubfifting in air and water, it is applicable to no animals. Although reptiles can remain much longer under water than the mammalia, or birds, they are obliged, as their refpiratory organs are only calculated for breathing air, to come fooner or later to the furface for this purpofe; and they are drowned, like any warm-blooded animal, if detained in the water beyond that time. To enable an animal to exift equally in air and water, it fhould have lungs and gills; that is, it fhould have the power of breathing air, like the mammalia and birds, and of breathing water, like fifhes; and it fhould be able to ufe either of thefe methods, to the exclufion of the other. But we know of no fuch animals. The larvæ of frogs and falamanders, the proteus anguinus, and the firen lacertina (fee the latter part of this article), have indeed branchiæ and lungs; but as far as our knowledge hitherto goes, none of thefe could live out of the water. The lungs of the tadpole, and of the larvæ of falamanders, are defigned for the fervice of thofe animals in their fubfequent ftage of exiftence; but do not give them the power of living in air: and the lungs, either of the proteus or firen, do not feem fufficient to enable them to difpenfe with the office of the branchial appendages. In its etymological fenfe, then, the term amphibious is not applicable to any animals we know of.

Linnæus

Linnæus places among his amphibia reptiles who never go into the water, and fome fifhes which never quit it. He could not fail to experience great difficulties in naming a clafs fo ill conceived as that of his amphibia; confequently, this appellation is objectionable, as being vague and obfcure; the genera comprehended in the Linnæan clafs amphibia, are too ill afforted to admit of their having a common name fuitable to all. Daubenton divided them into two claffes, naming one oviparous quadrupeds, and the other ferpents. Lacépéde adopted thefe two claffes, and placed between them a third, that of oviparous bipeds. Hermann of Strafbourg, in his "Tabulæ affinitatum Animalium," propofed to fubftitute, for the term amphibia, that of cryerozoa. "Si in novorum nominum impofitione gloriam more multorum quæreremus, et ea re fcientia promoveretur, cryerozoa apte vocari poffe putaremus, quia omnem fere naturam eorum animalium vox ifta exhaurire videatur. Κρυερος enim non modo frigidum, fed et horridum luridumque fignificat." Hermann, Tab. affin. Anim. p. 218.

Without entering further into the objections againft the appellations juft enumerated, we adopt that of reptiles, already employed by many modern naturalifts, and particularly by Cuvier, in his "Tableau Elémentaire d'Hiftoire Naturelle." In fact, in the progreffion of the oviparous quadrupeds, as well as in that of ferpents, the belly moves againft the furface of bodies, over which they pafs.

General Obfervations.—Referring to the article CLASSIFICATION for a view of the genera comprehended under thefe divifions, we prefix to the more detailed furvey of the anatomy of reptiles, a fhort fummary of the principal anatomical characters of the four orders into which the clafs is divided.

1. The CHELONIAN order; Teftudines. Body inclofed in a bony fhell. They refemble birds in having the mafticating furfaces of their maxillary bones covered by ftrong cutting horny plates. Body fupported on four limbs, terminated by a tail, and covered in almoft all by fcales. They copulate; fecundation takes place internally: the female lays eggs, covered by a firm calcareous fhell: the young animals come out without incubation, merely by the heat of the atmofphere; and they undergo no metamorphofis. Stomach larger than in the other reptiles, and inteftinal canal furnifhed with a cæcum. The heart has two auricles.

2. SAURIAN order, or Lizard kind. They refemble the former very nearly in the ftructure of their principal internal organs. They have firm bones, like thofe of the mammalia: curved and long ribs, and a fternum. Teeth fet in the jaw. The two branches of the lower jaw confolidated. A trachea compofed of cartilaginous rings, an os hyoides and larynx, capable of producing founds, at leaft in fome individuals. Heart with two auricles. A fimple penis in the male. There is a real internal copulation; the female lays feparate eggs, generally covered with a firm fhell, depofiting them on dry ground, or in holes. The young ones come out of them, and undergo no metamorphofis. The fkin is furnifhed with numerous plates or fcales. Body elongated, and ending with a tail. Feet, often high, and ftrong enough to fuftain the body above the ground in progreffion. Some are quadruped; others biped, having either fore or hind feet. Toes furnifhed with nails: generally five in number; but there may be four, three, two, and even one.

3. OPHIDIAN order; Serpents. They agree with the two former orders, in having firm bones, curved and long ribs, a larynx and trachea, capable of producing a flight hiffing in moft. An external organ of generation in the male. A real internal copulation: the female lays eggs covered with a calcareous fhell, which fhe depofits in holes filled with leaves, under the roots of trees, in warm and rather moift fituations. The young ones, when they quit the egg, are like their parents. They differ from the preceding orders, in having a long, eel-fhaped, flexible body, covered with a fkin, either furnifhed with fcales or plates, or naked, unprovided with feet, and terminated by a tail, often very long. Numerous long curved ribs, not united together, as there is no fternum. The branches of the lower jaw not united in front. Upper jaw confifting of four branches. Simple, fharp, and numerous teeth; and long, curved, tubulated fangs, in addition to thefe, in the venomous kinds. They creep along the ground by undulations of their body. Excepting the ophifauri, they have no external auditory openings. Heart with a fingle auricle. Double penis. Eggs covered with foft calcareous fhells.

4. BATRACIAN order; Frog kind. They refemble the preceding orders in having a tail; excepting the frogs and toads in their perfect ftate: a trachea and larynx, capable of producing found. Like the chelonian and faurian reptiles, they have feet, and fimple jaws, *i. e.* not formed of two branches, moveable on each other. In common with the faurian and ophidian orders, they poffefs teeth fixed in the jaws; and with the ophidian, a heart with a fingle auricle.

Many characters diftinguifh them from thefe three orders. Their naked fkin, which is warty or tubercular, more or lefs moift, and nearly fimilar to that of the cecilia, the laft genus of the ophidian order. Softnefs of the bones; a fternum without ribs in the frogs and toads: rudiments of ribs and no proper fternum in the falamanders: true curved ribs furrounding the body in the proteus and firen. Four feet, or two only. They all fwim; thofe with long hind legs and no tail leap; the tree-frogs attach themfelves to leaves by the round tubercles of their toes: thofe with four equal limbs, or two only, crawl and fwim, but do not leap. An external tympanum in the tree-frogs, frogs, and moft toads; no external ears in the others. No external organ of generation in the males, nor any internal real copulation. The female lays eggs in the water, or humid earth, and the male fecundates them as they pafs out; or in the ovo-viviparous fpecies, as the land falamander, the feminal liquor of the male is abforbed by the fexual organ of the female. The ova are without fhells; from them proceed fmall animals, called tadpoles, which undergo various changes, before reaching their perfect ftate. They have branchiæ in their tadpole condition, and thus approach to fifhes.

Notwithftanding the obvious differences of organization in the different reptiles, as the turtle, lizard, ferpent, frog, and falamander, we may remark that their ftructure does not deviate effentially in its general plan from that of the human fubject. They have a bony vertebral column, and all the principal organs found in man, but with more or lefs ftriking modifications.

Reptiles have fome relations, in their organization and habits, with other vertebral animals, particularly with fifhes. This is feen in the true branchiæ of the batracian larvæ and firen; in the fcales of the fkin in lizards and ferpents; in the polygonal horny plates of the teftudines, correfponding to thofe of fome cartilaginous fifhes; in the elongated form and habits of the firen, like thofe of the eel-fhaped fifhes.

The form of the body prefents great differences in the reptiles; nearly all the chelonians, faurians, and batracians have four feet; and there are only two faurians with two feet. In the chelonians, the body is orbicular, more or lefs convex, inclofed in a bony cafe, and terminated by a fmall tail; the toes are feparate and diftinct in fome, palmated and fin-like in others. All the faurians have an elongated body, covered with various kinds of fcales, and terminated

by

by a very flexible tail, often compofed of articulated rings. In the very elongated form of their body, the chalcides refemble ferpents, though, in other refpects, they are true faurians. The fkin is quite naked in all the batracians; they have four feet; fome have no tail, a ftout, thick body, and the hind legs longer than the front; others have the fhape of a lizard, being furnifhed with a tail, and having feet of equal length. Laftly, ferpents have a very long, cylindrical body, covered with fcales, and without limbs. Thefe variations of figure muft neceffarily be attended with modifications in the form and pofition of organs; the internal arrangements will correfpond with thefe outward figns.

Although the animals of this clafs differ very confiderably in outward form, as well as in the general bulk of their bodies, they agree very nearly in the effential points of their organization, and more particularly in the functions of their animal economy. We may inftance the mode of taking their food; the long abftinence of which they are capable; their oviparous generation; the length of time, for which they can bear an interruption of refpiration; their tenacity of life and extraordinary power of reproduction; and the low temperature of their bodies. The laft points, of animal heat and reproduction, two exceedingly interefting fubjects of inquiry, which have been inveftigated of late years with great induftry, form the moft ftriking differences between cold and warm-blooded animals; the latter alone poffeffing that remarkable property of maintaining in themfelves a temperature confiderably exceeding that of the medium in which they live, while the former are diftinguifhed by the wonderful extent of their power of extending or reproducing injured or loft parts.

An accurate knowledge of the ftructure of reptiles is not only important from its fubferviency to the claffific arrangements of natural hiftory, and highly interefting from expofing to us new and rich fcenes in the vaft domains of nature, new forms of life, and frefh modifications of organization, accompanied with fingular changes of functions already familiar to us in other fhapes; but it acquires additional intereft from the great ufe which phyfiologifts have made of different reptiles in their experimental elucidations of the human economy. We muft furvey in a general view the ftructure and economy of thefe animals, and compare them with thofe of the warm-blooded claffes, before we can determine how far the conclufions, drawn from experiments on reptiles, concerning the heart's motion, irritability, the action of the nerves, the effects of opium, &c. &c. can be transferred to the human body.

Organs concerned in the Vital Functions.—The *mouth* is fituated at the extremity of the fnout, and directed tranfverfely. If we fancy the head to be divided by a horizontal cut, extending from before backwards, to its very pofterior part, we fhall have a juft idea of the mouth of a reptile. The cranium is very fmall in this clafs, and the head confifts almoft entirely of the two jaws. The lower is articulated towards the back of the head, and thus allows the opening between the two mandibles, conftituting the mouth, to be very confiderable. Almoft all reptiles fwallow entire animals, and thus require this extenfive opening. The margins of the aperture confift fimply of the maxillary arches, which are not covered or enclofed by any thing deferving the name of lips. In no cafe is there any maftication; and the food or prey is taken by the teeth or tongue, fo that a moveable covering of the jaws, fimilar to the lips and cheeks of the mammalia, is not neceffary either for confining fubftances fubjected to the action of teeth as organs of maftication, or for the purpofe of reaching or feizing food.

The horny coverings of the mandibles, completely naked, and not concealed even by the fmalleft fold of fkin, form the fides of the entrance into the mouth in the chelonian reptiles. Their food confifts of marine vegetable productions, teftacea, infects, &c. and does not require fo large an opening for its introduction, as when confiderable animals are fwallowed whole. The mouth is confequently fmaller in this than in either of the other orders; and does not extend completely to the back of the head.

The family of tortoifes, which Geoffroy has called trionyx, offers a remarkable exception to what we have ftated about the abfence of lips: they have thefe folds, and a moveable probofcis at the end of the fnout. "The exiftence of lips in thefe tortoifes is an anomaly, the more likely to furprife us, inafmuch as the affinity of thefe reptiles to birds feems to affign a motive for the abfence of lips, and alfo for the exiftence of the horny coverings of the mandibles." Geoffroy St. Hilaire, Mem. fur les Tortues molles; Annales du Mufeum, v. 14. pl. 1. p. 9.

In the faurians, the flit of the mouth goes to the very back of the head, far behind the ear. Its appearance is very formidable in the crocodile, where the hard ftrong jaws project into a large fnout, and are armed with fharp powerful teeth, deftitute even of gums: thefe jaws open to the very back of the head, and difclofe a tremendous throat. The mouth is as large proportionally in the other faurians; but their fize is too infignificant and their habits too harmlefs to allow of their infpiring that terror, which the formidable weapons of the crocodile fo juftly caufe. The ophidians have not only a mouth equal in its tranfverfe meafurement to the diameter of their body; but they poffefs alfo the means of enlarging this aperture, fo that they can fwallow creatures whofe diameter exceeds their own. The batracians have an opening as large as the fize of the head will allow. In the latter, as well as in the ophidian, and moft of the faurian reptiles, the integuments make a fmall fold at the edge of each jaw; thefe folds meet when the mouth is clofed, fo as to hide the edge of the jaws, but they poffefs no power of motion.

In the tadpole, in the proteus and firen, the mouth is much fmaller than in the other reptiles; and they poffefs folds more deferving the name of lips. In the former there is a kind of horny apparatus within thefe lips, forming fomething like a beak. In the fmallnefs of its mouth, and in thefe horny jaws, the tadpole is remarkably diffimilar to the perfect animal.

The Jaws.—In confidering the jaws and their mufcles, the teeth, and the tongue, we muft bear in mind that thefe organs are calculated merely for feizing their food, and conveying it to the throat; in no cafe does the food undergo any maftication, as in the mammalia.

No reptiles have an upper jaw moveable on the head, like that of birds: the fuperior maxillary bones are in truth articulated moveably with the head in ferpents, and may be extended and retracted, or moved laterally, as we fhall defcribe prefently; but, in general, the cranium and upper jaw are united into one piece, fo far as their motions are concerned.

The moft oppofite opinions have prevailed refpecting the crocodile, even down to the prefent time. Herodotus firft obferved, that it is the only animal poffeffing an upper jaw moveable on the lower, which remains fixed. The fame opinion was generally held by the ancients, as Ariftotle, Pliny, &c.; and feveral moderns fpeak in the fame way, as Maregrave, Marmol, Jacobæus, Vefalius, and the Jefuit Miffionaries at Siam, who had opportunities of obferving the living animal. But the anatomifts of the Academy of Sciences

Sciences (Perrault and Duverney) undertook to demonſtrate the falſehood of the opinion of Herodotus. Geoffroy, one of the French ſavans, who attended the Egyptian army, has given us an account of the matter, which ſettles all theſe diſputes, by proving that the ſtatement of Herodotus is almoſt rigorouſly true; and that the crocodile is the only known animal, whoſe upper jaw, including within its branches the cranium, is moveable on the lower jaw, which poſſeſſes only an almoſt inſenſible degree of motion. "Nothing can be more paradoxical than the head of the crocodile: every thing which is placed laterally in other animals, as the moving powers of the jaw, &c. is thrown behind. The temporal bone itſelf extends backwards far behind the cranium, is elongated, and transformed into a double condyle. We have in fact nearly deſcribed the crocodile's head, when we ſay that it conſiſts of two mandibles; for the cranium is ſo ſmall, and out of place, that it eſcapes notice at firſt. We find it below, and a little in front of the occipital criſta. The brain is ſo far forwards, that the eye and ear are above and a little behind it.

"The lower jaw is one-ſixth longer than the upper, with the cranium: it preſents a cavity with a double ſurface, in which the condyle of the temporal bone is articulated by ginglymus. The occipital condyle is in the ſame line as the temporal condyles: thus the head is really held at its articulations, like the lid of a box by the hinge, and is confined entirely to motions upwards and downwards. When a living or ſtuffed animal is examined, it is difficult to believe that the head ends at the extremities of the jaws. There is a regular fullneſs of the front of the neck, which might be regarded as the frontal part of the head: this ariſes from the enormous temporal muſcles, which lie between the recti and obliqui. The latter, ariſing from the cervical vertebræ, and inſerted in the occipital criſta, elevate the head upon the neck, making it deſcribe an arc of 45°. The ſkin behind the occiput being thin, yields to the motions of the head; while the lower jaw, on the contrary, is incloſed in a kind of ſheath of hard, rugous ſkin. If there were a muſcular force capable of drawing it down, this covering would impede its deſcent, while it is ſtill further confined behind: the long proceſs ſituated beyond its articular ſurface, deſcribing a curve, approaches the ſkin exactly at the point where it is armed with a long ſcale, which offers an almoſt invincible reſiſtance to the elevation of the condyle, and conſequently to the depreſſion of the jaw. Yet it is not entirely fixed, as Marmol imagined, who ſtated that it forms a ſingle bone with the ſternum. Two ſmall muſcles have the power of moving it ſlightly." (Annales du Muſeum, tom. ii. p. 38, et ſeq.) This deſcription is accompanied with an excellent figure of the ſkull, in the elevated ſtate of the upper mandible. An analogous figure of the whole head is given by Humboldt, Recueil d'Obſ. de Zool. & d'Anat. comparée, tom. i. pl. 4. From the figures of the Nilotic crocodile, in Blumenbach's Abbildungen Natur Hiſtoriſcher gegenſtände, N° 26; and of the St. Domingo crocodile, in the Annales du Muſ. tom. ii. it appears, that the animal moſt frequently exhibits this elevation of the upper jaw. It cannot be neceſſary to point out how the raiſing of the entire cranium and ſuperior mandible, juſt deſcribed, differs from the motion of the upper jaw upon the cranium: this has been already done by Blumenbach. See Syſtem of Comparative Anatomy, p. 111, note 8.

The length of the lower jaw is much more conſiderable in compariſon to that of the upper in reptiles, where it is articulated far back, and is even prolonged beyond its articulation, than in mammalia and fiſhes, where this articulation is placed more forwards. Its compoſition is more complicated in the reptiles, than in any other order. In the green turtle (teſtudo mydas) it conſiſts of ſeven diſtinct pieces, a middle one forming the arch, and three others on each ſide, forming a continuation of its branches. The fartheſt of the three penetrates like a wedge between the two others, and forms a great part of the articular cavity. In many of the ſaurians the number is ſtill greater: the lower jaw of the Nilotic crocodile, and of the caïman (croc. americanus), has no fewer than twelve pieces, arranged as follows. As the two branches are diſtinct, and united by a ſuture, each of them muſt be compoſed of ſix pieces; 1, one, in which all the teeth are implanted; 2, another, lying along the internal ſurface of the former, without reaching to its anterior extremity; 3 and 4, two others articulated with the preceding; *viz.* an inferior one prolonged to the poſterior extremity of each branch, a ſuperior extending as far back as the other in the Nilotic crocodile, but not ſo far in the caiman. 5. The greateſt part of the articular cavity is excavated in a fifth piece within the two former, and conſtituting the inner and ſuperior part of the portion beyond that cavity. 6. Laſtly, a ſixth piece forms the front and inner part of the orifice of the dental canal. The lower jaw of the tupinambis (lacerta monitor) is alſo compoſed of twelve pieces, two of which form the coronoid proceſſes, while the other ten are analogous to thoſe deſcribed as entering into the formation of the lower jaw of crocodiles, excepting the laſt. There are eight or ten in moſt of the other ſaurians. We find four in each branch in the genus anguis; an anterior one united to its correſponding piece in front, and three poſterior ones joined to the former. There are only four altogether in the amphiſbæna. The two laſt mentioned genera are the only ophidian reptiles, in which the jaws are not ſeparated in front. In all the others there is a ſeparation, and each branch has only two diſtinct pieces; an anterior, in which the teeth are implanted, and a poſterior: they are united by ſuture, and vary in relative length, according to the number of teeth. The very open arch, compoſing the lower jaw of the batracian order, is made up of ſix pieces; the middle of which are the moſt ſlender.

The anterior angle, formed by the union of the two branches, depends on the form of the ſnout in general, on the figure of the two branches, the preſence or abſence, number and ſize of the teeth, &c. It is rounded and very open in the chelonian reptiles, and more ſo in the batracian. In the ophidian order, which have the branches of the jaws moveable, it is ſuſceptible of change, according as their extremities are approximated or drawn aſunder; indeed in the former caſe only can it be properly ſaid to exiſt at all. It is rounded in the amphiſbæna; more angular in the anguis; ſtill very obtuſe in the geckos (lacerta gecko), which have wide jaws, with the branches of the lower curved only in the horizontal direction; it is leſs ſo in the cameleon and ſtellio (lacerta ſtellio), the ſcinks (lacerta ſcincus), and the lizards, although in all theſe the two branches are only joined by their extremities. It is acute in the tupinambis and iguana, in which the branches, ſomewhat curved in the vertical direction, are approximated for a longer ſpace. The Nilotic and Gangetic crocodiles differ very much in this reſpect. The two branches are united in the latter in the greateſt part of their extent, as in the cachalot, and conſequently form a long bill, in the edges of which the two rows of teeth are implanted. In the former, on the contrary, the branches remain ſeparate, and only approximate towards their extremity, increaſing a little in thickneſs at the ſymphyſis.

The portion of the bone, which is incurvated towards the cranium in moſt of the mammalia, and conſtitutes

 the

the afcending branch of the jaw, does not exift in reptiles.

Motions of the Jaws.—Reptiles may be divided into two orders, according to the conformation of their maxillary bones, and the kind of motion of which they are fufceptible. In the firft would be placed thofe which have the lower jaw only moveable, as the lizards, the teftudines (tortoife and turtle), the frogs, the falamanders, and the genera anguis and amphifbæna among the ferpents. The fecond would include the colubres, and the venomous ferpents, which can move both jaws.

The general difpofition of the articulation is nearly the fame in reptiles as in birds (fee BIRDS, in *Comparative Anatomy*). Inftead of a condyle at the pofterior extremity of the jaw, an articular furface is excavated to receive an eminence bearing confiderable analogy to the os quadratum of birds, and differing from it only in not being fo moveable; often, indeed, it is only a fimple prolongation of the temporal bone. To this moft inferior point of the cranium, and to an articular furface nearly tranfverfe in its direction, and fhaped like a condyle, the lower jaw is articulated by a glenoid cavity, of which the middle part fometimes prefents a rifing line, converting it into a kind of pulley. Behind this articular cavity there is often a more or lefs confiderable bony procefs, affording attachment to a mufcle analogous to the digaftric.

The moft remarkable differences requiring our notice here are, the form of this prominence or condyle of the temporal bone; the greater or lefs prolongation of the procefs behind the articulation; the fituation and extent of the temporal foffa; and, laftly, the exiftence or abfence of the eminence occupying the fituation of the coronoid procefs.

In proportion as the temporal eminence is carried backwards, the jaws approach more nearly to each other in their longitudinal direction. We fee this in the crocodile, falamander, frog, turtle, and tortoife. When, on the contrary, it defcends vertically, or very obliquely, and is very elongated, as in the cameleon and iguana, it forms a kind of pedicle to the lower jaw, which, by feparating it from the cranium, produces a much more confiderable interval between the jaws. Several kinds of lizards, as the lacerta agilis, draco, &c. occupy the intermediate fpace between thefe two extremes.

The crocodile has the largeft procefs for the attachment of the digaftricus. It is fenfibly diminifhed in the cameleon, the gecko, the tupinambis, and the teftudines; and we fee nothing of it in the pipa, the toad, frog, and falamander.

All four-footed reptiles have very deep temporal foffæ; they are united to the cavity of the orbit. In fome fpecies, the two cavities are feparated in front by a bony circle, as in the teftudines, the crocodile, the dragon, and the other lizards; but in the pipa, the frogs, and falamanders, there is no orbital circle.

There is, in the crocodile, a confiderable excavation on each fide of the cranium, behind the orbit, terminating below in the temporal foffa, and wanting in the crocodile with bony eyelid (Crocod. palpebrofus, Cuvier). It is bounded externally by a bone correfponding to the fquamous portion of the temporal, which joins the lateral frontal bone, and thus forms a fecond kind of zygomatic arch. The fize of this excavation differs much in the different fpecies. No doubt it contains mufcles. But we find no exprefs and fatisfactory defcription of it and its mufcles, nor of the mufcles of the jaw in the writings of the French naturalifts already quoted, on the fubject of the crocodiles.

The coronoid procefs of the lower jaw is not prominent in reptiles. There is a mere rudiment of it in the teftudines, the cameleon, and fome lizards, as the iguana, but there is no trace of it in the crocodile, the frogs, and falamanders.

The mufcles of the jaw, in the oviparous quadrupeds, are analogous to thofe of the mammalia, and refemble them in number.

The mafleter is large and diftinct in the tupinambis, occupying all the fpace comprifed between the pofterior edge of the orbit and the meatus auditorius. It is directed obliquely from behind forwards, fo that it raifes and carries the jaw backwards. This mufcle is fmall in the agame marbré (lacerta marmorata), and the turtle. It is fo flender, that it can fcarcely be diftinguifhed from the lower part of the temporal.

The temporal mufcle is very large in the turtle, occupying all the temporal foffa, and forming the back of the orbit. It is much fmaller in the tupinambis and common lizard, in which it is almoft entirely concealed by the mafleter.

The pterygoidei are, in general, but imperfectly diftinguifhed from each other. They envelope the whole branch of the jaw towards its extremity in the tupinambis; their fibres are in a manner twifted. They elevate the jaw and carry it forwards; thus they act in an oppofite direction to the two preceding mufcles. The fame mufcles are flat and thin in the turtle; their fibres are nearly tranfverfe, fo that they can move the lower jaw more directly from fide to fide.

In all thefe reptiles the mufcle analogous to the digaftric is flat and triangular; the broad portion is fixed to the cervical ligament behind the occiput, and the point terminates at the extremity of the jaw, behind its articulation, and near the pterygoid mufcles.

After defcribing the mufcles employed in moving the jaws of the turtle, Perrault afferts, in his "Mémoires fur les Animaux," that it has more power in its jaws than moft other animals, that it can cut very hard and ftrong fubftances, and that the head of a fmall turtle has been feen, half an hour after it was cut off, to ftrike its jaws together with a noife like that of caftagnettes. Daudin relates the following circumftance, communicated to him by a Dutch naturalift, who refided feveral years in India. "When we landed in Table bay, we took feveral hawk's-bill turtles (teftudo imbricata), whofe ftomachs were filled with marine plants, and thick fhells, which they eafily break down with their horny gums. Three, which could not be brought on board, were tied to the trunk of a tree, with a thick cable, but when the failors returned on the following morning, they found that thefe turtles had contrived to turn over on their bellies, and had then cut, with their gums, the cables with which they had been faftened." Hift. Nat. des Réptiles, in the edition of Buffon, by Sonnini, t. i. introduction, p. 38.

The two jaws are not moveable in all the ferpents. They may be divided into three orders. 1. Thofe with the branches of the lower jaw confolidated, and confequently not poffeffing any power of thrufting forward the upper jaw, or moving it laterally. 2. Thofe with the branches diftinct, and united in the recent ftate by an elaftic ligament. There are two modifications of the latter; they may either have merely the power of feparating the two jaws; or they may, at the fame time, feparate the jaws, and carry forwards a part, or the whole of the upper. We fhall fpeak of the motions of the jaws according to this divifion, firft defcribing the bones, and then the mufcles.

The Bones.—In the ferpents, with the lower jaw confolidated, the head is fhaped nearly as in the lizards. This is the cafe in the anguis and amphifbæna, the cæcilia, acrochordus, and hydrophis. In the genus anguis the head very clofely refembles that of the iguana. The arch of the upper jaw

jaw is uninterrupted, and correfponds to the curve of the lower; the concavity of the palate is nearly complete in front. The palatine arches are directed backwards, and united to the condyloid pedicle of the temporal bone. This pedicle is fhort, and nearly vertical, and excavated behind for the attachment of the digaftric mufcle. The lower jaw has a fmall procefs behind its articulation for the attachment of the mufcles, which deprefs it; and another towards its pofterior third portion, analogous to the coronoid, for the elevating mufcles.

In the amphifbæna, although the general configuration is a little changed, nearly the fame arrangement is met with. The whole upper jaw is lefs feparated from the cranium; the concavity of the palate is nearly complete. The palatine arches are much larger. The condyloid pedicle of the temporal bone, inftead of being vertical, is continued nearly horizontally forwards. In proportion to the cranium, the lower jaw is much fhorter; and it is articulated to the condyle by its pofterior extremity. It is very wide behind, to produce the coronoid procefs. The orbit and temporal foffa are completely confounded; they are bounded by prominent bony criftæ, as in the carnivorous mammalia; hence, on firft view, the head of an amphifbæna might be fuppofed to belong to one of the cheiroptera.

The ferpents of the fecond kind, whofe lower jaw is formed of two diftinct branches, and in which the upper is capable of being feparated, but not carried forwards, are all the non-venomous colubres, and the boas. The conformation of the upper jaw, in the latter, is very different from that of the lizards, although the bones are nearly the fame, as we fhall explain in the ofteology of the head. The offa incifiva are not always furnifhed with teeth; fometimes even, as in the boas, they do not unite the fuperior maxillary bones. All the other bones of the jaw are moveable on the cranium, which ferves merely as a point of fupport.

The fuperior maxillary bones are two long branches, in which the teeth are implanted; they form the outer edge of the palate. They are articulated by two points; firft towards their middle, as a lever of the firft kind, on a fmall bone analogous to the os malæ, and forming the anterior edge of the orbit: nearly at the fame point, but towards the inner fide, the fuperior maxillary bone has a procefs, which flides in a groove, and refts on the palatine arch. It moves on thefe two furfaces, playing backwards and forwards. The anterior extremity of this upper maxillary bone is free: the pofterior receives the end of a particular bone, ferving to unite it to the palatine arches.

The palatine arches are the two internal bony branches themfelves, formed of two parts. An anterior, which is free in front, and articulated by three points; behind, with a bony branch, which proceeds towards the extremity of the lower jaw within its articulation, and appears to form a continuation of it; on the outfide, with a particular bone, uniting it to the maxillary arch; and above, with the bafis of the cranium, in front of the orbits. The pofterior portion of the palatine arch is analogous to the pterygoid alæ or laminæ. It is articulated by three points; 1ft, in front, with the pofterior extremity of the firft portion; 2d, behind, with the lower jaw towards the infide; 3d, on the outfide, and towards its anterior part, with the bone uniting it to the maxillary arch. Laftly, the third palato-maxillary is a piece nearly cylindrical in its middle, flattened and widened at its two extremities, by which it is fupported, being articulated, on the outfide, to the pofterior extremity of the maxillary arch, on the infide, towards the middle and outfide of the pterygoid portion of the palatine arch.

In confequence of this fingular formation, the whole upper jaw is, as it were, fufpended and diftinct from the cranium, and influenced by the motions of the lower jaw. When the pofterior extremities of the latter are feparated, the pterygoid arches are moved apart. They carry with them the pofterior extremities of the palatine and maxillary arches, while at the fame time the anterior extremity is moved inwards. On the contrary, when the two internal edges of the pterygoid laminæ are brought together, or, what is the fame, when the articular extremities of the lower jaw tend to approximate, the anterior ends of the palatine and maxillary arches are carried outwards, and feparate from each other.

The ferpents of the third order, which have jaws fufceptible of feparation, and which at the fame time can carry forwards the fuperior maxillary bones, properly fo called, exhibit but a flight modification of the ftructure defcribed as belonging to the preceding divifion. Their pterygoid arches are articulated with the lower jaw, towards its extremity, on the guttural afpect. They alfo receive the bone which is to join them to the palatine arches; but the latter are very fhort, directed forwards, and only containing venomous teeth. This intermediate bone, therefore, goes above the fuperior maxillary, which is itfelf articulated in the front of the orbit, or the fhort and moveable cheek-bone. When the lower jaw is moved forwards, the palatine arch, carried in the fame direction, drives before it the bone which joins it to the maxillary. The latter, extremely moveable, is immediately turned up, or carried forwards, by moving on the cheek-bone, which caufes a complicated feries of motions.

The articulation of the lower jaw is the fame in the whole family. The temporal proceffes are prolonged pofteriorly: they receive an intermediate bone; analogous to that defignated by the name quadratum in birds. This bone is very fhort, and poffeffes little motion, in the fpecies which have the upper jaw fixed, and the inferior confolidated.

It is directed forwards in the amphifbæna towards the lower jaw, which is fhorter than the cranium by nearly one-third;—a circumftance which belongs only to this fpecies. In the anguis, the os quadratum defcends much more obliquely forwards.

In all the other fpecies the bone laft-mentioned is much longer. It fometimes defcends perpendicularly, as in the boas; but it is commonly directed backwards, as in moft of the colubres. The temporal extremity is generally widened and excavated by a fmall depreffion. The inferior extremity is rounded like a condyle, and received into an excavation of the pofterior extremity of the correfponding branch of the inferior maxillary bone.

From the nature of its articulation, the lower jaw of either fide is not only fufceptible of elevation and depreffion, fo as to open and fhut the mouth, by playing on the os quadratum, as is the cafe only in the genera amphifbæna and anguis; but it may alfo be carried outwards, and take with it the os quadratum, as is the cafe in the colubres and venomous ferpents, whenever the pterygoid arch is moved outwards. That is to fay, whenever the upper jaw is widened, the inferior muft follow its dilatation, becaufe the pofterior extremities of the pterygoid arches, being articulated with the internal part of the lower jaw, it muft move together with them. The arrangement of the mufcles accords very well with this formation, as we fhall proceed to defcribe.

Mufcles of the Jaws.—The maxillary mufcles of the genera anguis and amphifbæna, and probably of all the ferpents with a confolidated under jaw, refemble thofe of the common

common lizard: but they are very different in thoſe whoſe lower jaw conſiſts of two diſtinct pieces: we ſhall deſcribe them in the rattleſnake.

Here the muſcles of the lower jaw are concealed in the lips, and go round the mouth on each ſide. That which forms the anterior edge of the commiſſure of the lips is the ſtrongeſt, and ſeems to hold the place of the maſſeter. It ariſes by firm aponeuroſes from the tendinous ſheath, which contains the venomous gland. Its fibres form a conſiderable cord, which conſtitutes the whole thickneſs of the lower lip, and are inſerted in the upper edge of the inferior maxillary branch for almoſt two-thirds of its length.

The muſcle immediately behind is analogous to the temporal, and is much ſlenderer than the preceding. It is a muſcular faſciculus, of which the ſuperior extremity is fixed to the temporal excavation behind the orbit, and the inferior, after going backwards behind the commiſſure, is confounded with the inſertion of the laſt muſcle. It is obvious that the contraction of theſe two muſcles muſt approximate the jaws, and thus cloſe the mouth.

In the commiſſure of the lips, and behind the two laſt muſcles, we ſee another reſembling them in form, but much ſhorter. It occupies the inferior part of the os quadratum, and about the poſterior third of the jaw, at the outer edge of the dental canal. It is an acceſſory muſcle to the temporal and maſſeter.

The muſcle correſponding to the digaſtricus occupies the whole length of the back of the os quadratum, and terminates at the poſterior apophyſis of the maxillary branch beyond and behind its articulation.

The muſcles moving the upper jaw are more numerous. One ariſes, by aponeurotic fibres, from the capſule of the joint, between the maxillary branch and the os quadratum, and paſſes forwards and upwards towards the ſheath of the venomous teeth, being partly expended on that ſheath, and on the poſterior apophyſis of the ſuperior maxillary bone. Its uſe is evidently to draw down the venomous teeth, when they have been elevated.

Two other muſcles act on the pterygoid and palatine branches. Both are ſituated between the middle line of the baſis cranii and the palatine arches. The lower, ſituated immediately under the ſkin in the palatine foſſa, is a plane of elongated fibres, occupying the whole middle line of the cranium, and going backwards to the internal ſurface of the bony pterygoid plate, which it will carry inwards and forwards, ſo as to protrude the ſuperior maxillary bone, and elevate the venomous fangs, at the ſame time contracting the mouth by the approximation of the two internal arches.

The other muſcle, ſlenderer, and placed above the preceding, towards the baſis of the ſkull, extends from the anterior portion of the palatine arch, and the whole length of this arch, to the middle of the baſis cranii, croſſing the direction of the laſt muſcle, on which it is placed. When it contracts, it carries backwards the whole maſs of the upper jaw, at the ſame time approximating its two branches.

By means of this mechaniſm, ſerpents can twiſt their mouths in ſeizing objects, and dilate them extraordinarily, ſo as to ſwallow animals larger than themſelves. Their teeth ſerve merely for holding their prey; and the muſcles moving the bones, in which theſe teeth are implanted, cannot move them in ſuch a way as would be neceſſary for maſtication, but merely depreſs, elevate, approximate, ſeparate, protract, and retract them.

Lacépéde thus deſcribes the motions of the jaws in ſerpents. "While the teeth of one ſide are fixed in the prey which the animal has ſeized, and are therefore motionleſs, thoſe of the other ſide are carried forwards, penetrate the animal, drag it towards the throat, and there fix it in their turn; when the oppoſite ones are again advanced to repeat the ſame proceſs on their ſide. By theſe repeated alternate motions of the two ſides of the jaws, combined with their lateral expanſion, ſerpents are enabled gradually to ſwallow animals of a diameter exceeding their own." Hiſt. Nat. des Serpens.

The Teeth.—Their ſtructure has nothing peculiar in reptiles. The bone is compact and hard; the enamel thin; and, as they are always thin, there is none of the third ſubſtance called by Cuvier the cement. We are not acquainted with any facts concerning the ſucceſſion of the teeth in reptiles;—whether they have two ſets, or that the firſt grow conſtantly, or that the jaws are elongated anteriorly, &c. The crocodile forms an exception to this remark: we are indebted to Cuvier for a very intereſting account of the ſucceſſion of their teeth, which we ſhall ſtate preſently.

The chelonian reptiles, like birds, have no teeth, properly ſo called: the horny ſubſtance encaſing their jaws, and ſupplying the place of teeth, will be deſcribed at the end of this account of the teeth of reptiles.

The ſaurian, ophidian, and batracian reptiles may be compared to the cetacea; as they do not maſticate their prey, the teeth are calculated merely to hold, and not to divide it: hence they have much leſs influence on their economy than thoſe of viviparous quadrupeds. They accord, however, tolerably with the natural genera and ſubgenera.

They are almoſt always the ſame in all parts of the jaw, ſo that they admit of diviſion into different claſſes, according to their configuration, only in very few ſpecies.

Sometimes they are attached to the two jaws only, as in the mammalia: this is the caſe with the ſaurians (excepting only the iguana, which has palatine as well as maxillary teeth); ſometimes they are implanted alſo in the palate, as in the ophidians, with the ſingle exception of the amphiſbæna. Their number is of leſs importance; firſt, becauſe it is conſiderable, and not accurately determined; ſecondly, becauſe they fall out without any hitherto aſcertained regularity, either in ſituation or time.

Teeth of the Saurians.—In the crocodile the enamel is more or leſs ſtriated longitudinally. The upper and lower teeth croſs when the jaws are ſhut. They are all conical, hollow, generally a little curved, and marked with two longitudinal projecting lines; an anterior and a poſterior one. The five or ſix poſterior teeth on each ſide are more obtuſe and compreſſed than the others.

In a living crocodile, which Perrault obſerved at Verſailles in 1681, he found that all the teeth were ſlightly bent towards the throat, and that this curvature was the moſt conſpicuous in thoſe near the end of the ſnout. When the jaws were drawn together, the teeth of each jaw paſſed into the intervals between thoſe of the other, ſo that an uninterrupted ſeries was viſible, as there are no lips to hide them. He ſays further, that the points of the upper teeth entered into excavations of the lower jaw.

The following account is derived from Cuvier's Obſ. ſur l'Oſteologie des Crocodiles vivans, in the 10th volume of the Ann. du Muſ. "The number of the teeth does not change with the age of the animal: a crocodile quitting the egg has the ſame number as one twenty feet long. I have aſcertained this fact in a ſeries of heads from an inch to two feet long. The back teeth may be a little concealed by the ſkin of the gums. The interior is always hollow, although

although the teeth, as in all other cafes, are formed by fucceffive ftrata.

" The capfule containing the new tooth is not enclofed in a feparate cell of the maxillary bone, as in the mammalia, but it lies in the bottom of the focket of the tooth which it is defigned to fucceed. This little fhell is firft on the internal furface of the root of the tooth in place; it occafions a groove in this part, by which, as it increafes in length, it penetrates into the hollow of the latter, and then deftroys by its preffure the pulp that filled its cavity, and furnifhed the materials of its increafe. Hence, at whatever age we may remove a crocodile's teeth, we fhall find, either in the alveolus, or in the cavity of the tooth itfelf, a fmall tooth, either in the form of a thin and fhort fhell, or more advanced and ready to occupy its place, when the old and enveloping tooth fhall have been difcharged. This fucceffion feems to be repeated as long as the animal lives: hence the teeth always appear fharp and frefh, and although larger, they are not much more worn in old than in young crocodiles. I have afcertained all thefe facts in a recent head, and in others preferved in fpirits of wine: and I could diftinguifh very clearly pulps and capfules fimilar to thofe of quadrupeds.

" This procefs was tolerably well underftood by Perrault and Duverney; Mem. pour fervir à l'Hiftoire des Animaux, v. iii. p. 167.

" As the teeth of the crocodiles are generally nearly perfect cones, and enlarge to their very bafis, how can they come out of the alveoli, of which the entrance is much narrower than their bafe? The new tooth, as it is developed and fills the cavity of the old, compreffes its fubftance againft the focket, deftroys its confiftence, makes it crack, and thus difpofes it to be feparated on the flighteft fhock at the level of the gum. The fragments are eafily thruft out of the fockets. We often find in the fockets of crocodiles, when changing their teeth, rings formed by the relics of the old teeth left behind, through which the new are making their way: and fuch are alfo found in the foffil jaws of true crocodiles.

" The bafe of the cone is generally not entire, but exhibits a more or lefs deep fiffure on its internal fide: it has been already mentioned that this is caufed by the preffure of the germ of the new tooth. While the germ is very fmall, this fiffure does not exift, and the germ itfelf never exhibits it.

" Although the teeth may be faid to be all alike, and arranged in an uniform feries, fome are rather larger than the reft; and the greater this inequality, the more irregular is the line of the jaws.

" Thefe larger teeth are either received into grooves of the oppofite jaw, or into holes, or they perforate it completely.

" In the caimans or alligators, the firft of Cuvier's fubgenera, (containing the American fpecies,) there are from nineteen to twenty-two teeth on each fide below, and nineteen or twenty above. The two firft of the lower jaw penetrate at a certain age the front of the upper jaw, and go completely through it. The fourth of the fame jaw are the longeft, and go into the holes of the upper jaw, in which they are entirely concealed when the mouth is fhut. The five front in the upper jaw are intermaxillary teeth.

" The firft and fourth of the lower jaw are long in all the three fubgenera; next to thefe come the eighth and ninth of the upper, the eleventh of the lower jaw in the true crocodiles and caimans. The caiman with bony eye-lids (crocodilus palpebrofus) has the twelfth below and the tenth above the longeft. After the fourth in the gavials (longiroftres) they are all nearly equal, fo that the jaws in thefe have not fo waving a line as in the other fubgenera.

" The fourth tooth below might be called canine, from its fuperior length, and becaufe it correfponds to the future between the maxillary and intermaxillary portion of the upper jaw.

" In the fecond fub-genus, or proper crocodiles, there are fifteen teeth on each fide below, and nineteen above. The firft of the lower jaw penetrate the upper; the fourth pafs into grooves, and are not lodged in cavities of the upper jaw.

" The gavials (longiroftres) have 25–27 on each fide below, and 27–28 above. The two firft and the two fourth of the lower pafs into grooves, not into perforations or cavities of the upper."

In the tupinambis of the Nile we find fixteen above, of which five are intermaxillary, thirteen below; all conical, and flightly bent backwards: the pofterior are the largeft and moft obtufe. In a tupinambis from the Moluccas there were fix above, and feven below, all compreffed and pointed.

The teeth of the common lizard, the iguana, and agame, are cutting, and more or lefs ferrated on the edges; they are all fo in the iguana, where feveral have fix or eight denticulations, and there are twenty or twenty-one teeth on each fide. The common lizard has twenty-one or twenty-two, but the anterior are not fenfibly denticulated, and the others have merely a groove. The agame has nineteen or twenty, all with three denticulations. In thefe three genera they increafe in fize from before backwards.

They are triangular, with a little groove before and behind, in the ftellio: there are fixteen or feventeen fuch on each fide, and two large conical canine teeth. There are, moreover, two fmall conical intermaxillary teeth above, to which nothing correfponds below.

The dragon correfponds to the ftellio in its teeth, except that the canine are proportionally longer than the incifors: the number is the fame. There is a good reprefentation of them in Blumenbach, Abbildungen Natur-Hiftorifcher gegenftände, No. 98.

The gecko has thirty-five or thirty-fix teeth on each fide, all of equal fize, clofe, fimple, flender, and pointed. The flat-headed gecko has feventy or feventy-four on each fide. There are twenty-two on each fide, above and below, in the fcink, all conical, fhort, clofely fet, and of equal fize.

The cameleon has, on each fide, eighteen above and nineteen below; of which the anterior are very fine, the pofterior much larger, and furnifhed with three points.

Teeth of the Batracians.—All thefe have teeth in the palate; as to the jaws, the falamanders have them in both, the frogs in the fuperior only, and the toads in neither.

The palatine teeth form, in the toads and frogs, a tranfverfe line, interrupted in the middle. They are implanted in the palate bones. They form two long parallel lines in the falamander.

The maxillary teeth are fmall, pointed, and clofely fet. The frog has about forty on each fide above, eight of which are intermaxillary; the falamander fixty, both above and below, and thirty on each fide of the palate.

Teeth of the Ophidians.—The ferpents are divided firft into two families, thofe which can, and thofe which cannot, feparate the two halves of the upper jaw. The former have no incifor teeth; but they have palatine, maxillary, and

 mandibular,

mandibular, or teeth of the lower jaw. The latter, having all the edge of the upper jaw furnifhed with teeth, poffefs, confequently, a kind of incifors.

The fecond family includes only the angues and amphifbænæ. The former, befides the conical flightly curved teeth of uniform fize, which they have in both jaws (eighteen or twenty above, and fifteen or fixteen below on each fide), poffefs others, very fmall and fhort, arranged in two rows, on the pofterior half of each palatine arch.

The other family is fubdivided into two tribes, the venomous and the non-venomous. In the latter there are conical, curved, and very pointed teeth, directed backwards along each maxillary, palatine, and mandibular arch; confequently there are four rows in the upper, and two in the lower jaw, all nearly longitudinal.

On the maxillary branch of the venomous ferpents there are only the hollow fangs, attached to the anterior extremity only; confequently, with the exception of thefe fangs, there are only the two palatine rows above, and the two rows of the lower jaw below.

The following is a table of the numbers of teeth on each fide in fome fpecies.

Names.	Incifor Teeth.	Maxillary.	Palatine.	Mandibular.
Boa conftrictor.	2	18	14	
Coluber molurus.	0	18	24	20
Coluber nafica.	0	16 of which the anterior are the largeft.	25 of uniform fize; very fmall.	18 the anterior largeft.
Coluber natrix (common fnake).	0	18 the pofterior largeft.	28	24
Rattlefnake (crotalus horridus).	0	1 and feveral rudiments not fixed.	14	5 or 6
Coluber haje.	0	the fame.	25 and a parallel row of fmall ones.	12—14
Coluber naja.	0	the fame.	the fame.	
Anguis fragilis (blindworm).				
Amphifbæna fuliginofa.	3 on each fide, and a middle one.	5	0	8

To this table, which is derived from the Leçons d'Anat. comp. of Cuvier, we add a fecond, drawn up by Palifot Beauvois, a French naturalift, who fpent many years in America, and whofe obfervations on ferpents are inferted by Daudin in the fifth volume of his Natural Hiftory of Reptiles.

Comparative

Comparative Table of the Teeth of feveral Serpents of North America, by Palifot Beauvois.

Names of the Species.	Upper Jaw. External Branch. Fangs on each Side.	Upper Jaw. External Branch. Common Teeth on each Side.	Upper Jaw. Internal Branch on each Side.	Lower Jaw on each Side.	Total Number of Teeth.	Food.
Crotalus duriffus.	1	0	6	5	24	Squirrels, various birds, rats, mice.
Cr. rhombifer.	1	0				Hares, fquirrels, birds, rats, mice.
Cr. miliaris.	1	0				Grafshoppers and other infects, worms.
Vipera berus.	1	0	10	10—12	44—48	
Coluber hetorodon (hognofe-fnake).	0	13 the two lower ones three times larger.	14	12—15	80—86	Infects, worms, field-mice, fhrews.
Col. erytrogrammus.	0	10	15—16	10—12	70—76	Birds, young turtles, frogs, falamanders, the amphibious rat.
Col. conftrictor.	0	12	28—30	16—18	112—120	As the laft; alfo fquirrels, lizards, tree-frogs.
Col. getulus (chain fnake).	0	8	18—20	10—12	72—80	Lizards, a ferpent with red and black bands, col. fulvius?
Col. fafciatus.	0	8	20—24	12—15	80—94	Small fifhes, frogs, infects, worms.
Col. fulvius.		the teeth not afcertained.				Grafshoppers and other infects.
Col. faurita.		the fame.				Tree-frogs, infects, worms.

Venomous Teeth and Gland.—We have ftated that the innocent ferpents have teeth along the maxillary edge of the upper jaw, and in the palate; that is, four parallel rows, two external or maxillary, two internal or palatine. The venomous kinds, inftead of the maxillary rows, have the venomous fangs at the anterior end of each fuperior maxillary branch; and they poffefs the palatine rows, as well as the innocent ferpents. There is no difference in the teeth of the lower jaw. The venomous fangs are much longer and thicker than the other teeth: they are conical, fharp-pointed, and perforated by a fine tube. They are moveable at the will of the animal, and can be drawn up from the jaw, or laid down at pleafure. They are contained in a kind of cavity formed in the gums, from which their point projects.

At the end of his account of Indian ferpents, Ruffel has given two finely engraved plates, reprefenting the appearances of the teeth in the venomous and innocent fpecies. In the coluber catenularis (tar-tuttah), an innocent ferpent, there are two marginal or maxillary rows of fimple teeth, and two palatine rows. The vipera elegans (katukah-rekula-podah) has alfo two palatine, but no marginal or maxillary rows. The teeth are furrounded by a fringed membranous covering, which almoft conceals them. The points alone appear, when the membrane is not entirely deprefled. At the anterior end of the maxillary bone, on each fide, is a large membranous fac, wrinkled, and containing the fangs. The vipera naja, or fpectacle fnake, has the palatine teeth, and two venomous fangs, like the laft; but the teeth are fmaller, the fangs fhorter, and the membranous fac lefs apparent. The bungarum-pamah, a fpecies of bungarus, has the palatine teeth, two fangs ftill fmaller than in the fpectacle fnake, and at the edge of the mouth, behind the orifice of the bag inclofing the fangs, three fmall teeth on each fide, which may be confidered as an imperfect maxillary row.

In the vipera elegans, the fang is fixed to a bony bafis, which is attached to the fuperior maxillary bone: this bafis is much longer in the fpectacle fnake, and has attached to it the three fmall fimple teeth already mentioned.

Behind the venomous fangs in the vipers and other ferpents, are other fmaller fangs, faid to be defigned to replace the former when they are loft.

Blumenbach has given an excellent delineation of the mouths

mouths of the boa conftrictor and the crotalus horridus, in his Abbildungen Natur-Hiftorifcher gegenftände, No. 37, to fhew the difference between the venomous and innocent kinds; an object of the greateft importance, both with regard to the fewer fpecies of the former, and the much more numerous of the latter kind, in order to warn mankind againft real danger, and preferve them from groundlefs terrors. "All ferpents (fays Blumenbach), whether venomous or not, have the double internal row of palatine teeth, and the inferior maxillary teeth, in common. But the innocent fpecies have moreover the whole outer edge of the upper jaw furnifhed with teeth: in the venomous kinds, this is toothlefs. But the latter have, at each anterior corner of the mouth, attached to the upper jaw, the long hollow fangs with a flit at their point. Thefe are connected with the venomous glands, of which they may be regarded as bony excretory ducts, to convey venom into the wound made by the bite.

"When, therefore, we fee in any fnake four rows of teeth in the upper jaw, *viz.* befides the two internal palatine rows, an external row on each fide running to the corner of the mouth; we may be fure that the fpecies is poifonlefs, and fo far innocent."

The *poifonous gland*, peculiar to the ferpents with fangs, and faid to be of the conglomerate kind, like the falivary glands of the mammalia, is fituated on each fide, behind the orbit, clofe to the branch of the fuperior maxilla, and almoft immediately under the fkin. It is covered by a membranous or aponeurotic femitranfparent fheath, fixed to the bones of the head in front of the gland. The excretory duct extends from the anterior part of the gland, immediately under the orbit, to the bony bafis of the fang, and opens into a canal excavated in the fang, running through it from above downwards, and terminating by an oblique aperture on its anterior furface. Two mufcles deftined to elevate the fangs, to deprefs the fuperior maxillary bones, and confequently to clofe the mouth, pafs along thefe bones from before backwards; one on the outer, and the other on the inferior fide of the gland. Thefe cannot act without compreffing the gland, and expelling its fecretion into the excretory duct. See a reprefentation of the gland and the furrounding mufcles in the coluber naja, Phil. Tranf. 1804, pt. 2. pl. 8.

In the article Poison of this work, there is an account of the appearance and fenfible properties of the fluid fecreted by the venomous gland of the viper, and of its effects on animals. We have a few additional points to mention on this fubject, as well as concerning the poifonous properties of fome other ferpents.

Fontana afferts, that the noxious qualities of the fecretion are retained for a long time, even in a dry ftate; and that perfons have fuffered from wounds inflicted by the fangs of vipers, and other venomous ferpents, preferved in fpirits or dried, even years after the death of the animal. The venom retains its colour and tranfparency in the dead tooth, and is ftill active enough to kill animals, if it be rendered fluid by immerfion in warm water. He alfo found it active after many months, when dried and powdered.

Leeches, fnails, and flugs, were not injured by the venom of the viper. The blindworm and common fnake were not affected. Of tortoifes, fome were infenfible to the bite, others died at the end of fome hours, when bitten by feveral vipers.

The bites of the vipers of thefe climates produce more or lefs alarming fymptoms in the human fubject, but are not attended with danger. A peafant, bitten by a viper in the little toe, had the foot, leg, and thigh fwoln in fix hours; the pulfe fmall and intermittent; there was head-ache, pain in the abdomen, laffitude, and oppreffion; he cried frequently and had no appetite. He gradually recovered in two days, under the ufe of vegetable decoctions and poultices, which probably did not contribute much to his reftoration. Daudin, Hift. Nat. des Reptiles, 8vo. introd. p. 138.

Lepechin mentions the circumftance of a young Bafchkir, ten years old, being bitten by a black viper (coluber prefter, L.) in the foot. "Son pied enfla extremement en moins d'une demi-heure, et il eprouvoit tant de douleur dans la partie bleffée, qu'il ne pouvoit pas remuer le pied fans être forcé de crier: la paleur extrême de fon vifage, fes yeux troublés, et fa refpiration génée, annonçoient trés-fortement le danger que couroit ce jeune homme, fi l'on n'y apportoit un prompt remède." Olive oil externally, and volatile alkali by the mouth, were the fuccefsful remedies. Daudin, v. 6. p. 168; (quoted from Lepéchin, Tagebuch einer Reife, &c. t. 2. p. 105).

While Charas was engaged in refearches for his work on the viper, he was bitten in the fore-finger. He immediately fucked the wound, made a ligature on the root of the finger, and another on the wrift. The bite gave him but little pain. He took fome fudorifics, which operated in a few hours, and he was cured.

Boyle fays that he cured a man bitten by a viper, by holding a red-hot iron near the wound for a quarter of an hour. The truth feems to be, that the effects of the bite are not confiderable in the human fubject; and this accounts better for the recovery of perfons bitten, than any virtues in the remedies employed.

The wounds inflicted by thefe animals are not. however, always fo free from danger. The viper cherfea (coluber cherfea, L.), fays Daudin, is very venomous, and its bite is often mortal. Linnæus employed olive oil in the cafe of a woman who had been bitten; but fhe died, although the remedy had been fuccefsfully employed in the bite of the black viper (vipera prefter). Daudin. v. 6. p. 148.

The wounds of many Indian, African, and American ferpents, are, however, fatal to the human fubject. The vipera cornuta of fouthern Africa, is defcribed by Paterfon as very virulent, infomuch, that the Bosjefmen and Namaquaws employ its venom for poifoning their arrows. Daudin, ibid. p. 189.

A captain Hall made fome experiments on the poifonous powers of the rattlefnake, of which he has recorded the refults in the Philofophical Tranfactions. The firft dog bitten by this animal died in fifteen feconds; the fecond at the end of two hours; and the third of three hours. He recommenced his experiments with the fame ferpent on the following day: the firft dog died in thirty feconds; another in four minutes. Three days after, a frog died in two minutes, a chicken in three minutes. A little time after, an amphifbæna was bitten, and died in eight minutes; and the ferpent, having fubfequently bitten himfelf, died in twelve minutes.

Sir Everard Hume has defcribed at full length the cafe of a man, who was bitten on the thumb and fore-finger by a rattle-fnake between four and five feet long in this country. He died eighteen days after the accident. Great fwelling of the whole limb up to the axilla enfued; the tumefaction did not extend to the neck, but there was a fullnefs down the fide, and blood was extravafated as low as the loins, producing a mottled appearance. A full trial was given to the volatile alkali, both externally and internally, and to other medicines of the like nature, as ether, brandy, &c. alfo to opium. The cellular fubftance had floughed over the whole fwelled part of the limb, fo that the fkin was feparated univerfally from the mufcles. For a further account of this cafe, and

and of some other cases of bites of East and West Indian serpents, see the Phil. Trans. for 1810, p. 75.

Russel, in his account of Indian serpents, has furnished us with the most ample and interesting details concerning the Indian poisonous serpents. Of these the cobra de capello, or spectacle snake (coluber naja), and the katuka-rekula-poda (vipera elegans), are the most dangerous. It appears, from a comparison of the effects of the venom of the Indian serpents, the rattlesnakes, and the viper in the mammalia, that the symptoms are nearly the same in all, but that the term of their duration differs. The bite of a rattlesnake destroyed a dog in England in two minutes; while that of the most venomous Indian snake has never been fatal to this animal in less than thirty-seven minutes. A chicken bitten by the gedi paragoodoo (bungarus cæruleus) was immediately affected with stupor; in ten minutes, it was incapable of remaining upright; a quarter of an hour after it was stretched on the ground, as if asleep; it made some efforts to rise, turning the head to one side and the other, became convulsed, and perished in half an hour.

A stout dog was bitten in the thigh by a serpent of the same species: he howled much from the bite, but walked about freely. He lay down in a quarter of an hour, and howled: when an attempt was made to make him stand by raising him up, it was found that the hind limbs were paralysed. He grew worse, ceased to howl, and vomited abundantly: he became benumbed, and remained lying on the side. He died in two hours, having had very bad convulsions.

A lean bitch, having been bitten near the groin, remained fifteen minutes without exhibiting any symptoms of suffering. In fifty minutes she lay down, and appeared much affected: on attempting to make her stand, it was discovered that the limbs were paralysed. She vomited a little, and was convulsed till death, which occurred seventy minutes after the bite.

Wounds inflicted by the spectacle snake, or coluber naja, had the same effects; also those of the katuka rekula poda. Death did not always follow in the latter case, particularly in a dog, who was bitten six times, and once inoculated with the poison. A horse was bitten by the last-mentioned snake on each side of the nose. Prodigious swelling ensued, and extended to the throat; the animal refused his food, vomited, and appeared greatly affected. He had an emollient fomentation, and recovered on the third day.

Experiments with the bodrou pam had the same results: swelling, numbness, paralysis, convulsions, and death.

Russel tried inoculation of the venom with needles, thread, &c. Of six trials on dogs, none proved mortal. Eight out of twenty-four were fatal in chickens and pigeons.

Several venomous and innocent serpents were exposed to the spectacle snake: it would not bite them until instigated to do it, and they died without attempting to retaliate. But Russel found, in repeated trials, that two of these animals did not hurt each other; they would fight, and wound each other, but these wounds were not mortal.

Many circumstances modify the results of wounds inflicted by venomous serpents: *viz.* the quantity of venom, the condition of the serpent as to vigour or weakness, the number of bites he has inflicted, the situation and nature of the part bitten, the size of the animal, &c.

There are many facts to prove, that the secretion of the venomous gland, which is so active a poison, when introduced into a fresh wound, is quite innocent, and probably inoperative, if taken into the stomach. The psylli, or serpent charmers, so celebrated among the ancients for curing persons who had been bitten by vipers, sucked the wound strongly and repeatedly. Recent wounds made by the fer de lance (vipera lanceolata) of Martinique, the venom of which is very active, are also sucked with impunity. Fontana swallowed the poison of the viper, both mixed with water, and pure; it had even a mild taste, instead of producing a caustic and burning sensation, as some have stated. The heads of vipers, with their fangs and glands entire, have been eaten by dogs without any ill effects; and even the head of the terrible rattlesnake, with all its venomous apparatus, has been employed, with the rest of the body, in making soup, which has been drunk with perfect impunity.

Having thus described the instruments with which nature has furnished the venomous serpents, for the purpose of attacking, killing, seizing, and swallowing their prey, we cannot be at much loss to understand how these objects are effected; yet the prevailing notions on the subject are calculated, instead of elucidating, to involve a plain matter in obscurity and mystery. These will be most effectually dispelled by the following statement of Palisot Beauvois, who had considerable opportunities of observing the habits of serpents in America. "Much has been written on the manner in which serpents seize their prey: some ascribe to them a kind of magical power, the effect of which is to charm and enchant the animals on whom they fix their looks; others, less fond of the marvellous, pretend that they inspire them with excessive alarm, that, not knowing what they do, they run from one side to the other, fly, return, and at last precipitate themselves into the jaws of the monster; a third opinion is, that serpents diffuse around a fetid odour, by the aid of which they suffocate birds, squirrels, rabbits, and the different animals on which they feed. It must be difficult to determine the means employed by these animals in a state of nature, for the purpose of seizing their prey; and it would probably be wrong if we were to suppose that the same means are adopted in all instances. Can we believe, for example, that the black serpent (coluber constrictor), which creeps with astonishing quickness, climbing shrubs, and not at all venomous, should employ the same means as the boiquira (crotalus durissus), a slow moving animal, never ascending the smallest plant, and furnished, like all the venomous serpents, with two fangs, the wound of which is so quickly fatal? Yet, if we may judge of these reptiles in a state of liberty, by what goes on when they are prisoners, they certainly create only a common alarm, such as any creature will feel, when endeavouring to escape from its enemy. The animals experience no enchantment, nor any attack of madness, when a serpent fixes his eyes on them. Serpents produce no bad smell, still less a fetid vapour, capable of suffocating animals. The boiquira eats indiscriminately all the dead birds brought to it. It will not eat frogs, which the black serpent, on the contrary, seems to prize highly. Fascination and charms are repugnant to reason: sorcerers and magicians exist no more among animals than men: cunning, address, and force, are in both cases a sufficient, as well as the only charm and power, to render the weak tributary and victim to the strong.

"I made, in conjunction with Peale, the following observations on a boiquira, which he had preserved alive for five years, and on a black serpent.

"A living bird (icterus pheniceus) was put into the cage with the rattlesnake, and remained there two days, without any offensive proceeding on the part of the serpent. The bird did not seem at all uneasy. As far as we could judge from the countenance, the air which it breathed was the same as it would be in an ordinary closed cage. During the two days, the reptile ate a dead bird of the same species as as that in the cage, which he never offered to touch. Another living bird, the loxia cardinalis, inftead of being frightened by finding himfelf in company with the boiquira, amufed himfelf with pecking at the cage, and eating millet-feed thrown into him; he changed his fituation frequently, and would even perch on the reptile's back; but he moved off at the found of the rattle. Several kinds of frogs, living and dead, were prefented to the fame ferpent; but he touched none. The black ferpent, on the contrary (coluber conftrictor), attacked the frogs immediately, and feemed to prefer the tree-frogs. He alfo fwallowed flies and other infects.

"A common rat was put into the cage with the boiquira, who immediately appeared animated; the rat, frightened, ran towards the fide oppofite to the reptile. The chafe lafted a few feconds, the animal ufing every effort to efcape, when the reptile, perceiving a favourable moment, flew at his prey, and bit it. The rat continued to run round the cage, but the ferpent remained quiet: the former, in about a minute, fwelled, became convulfed, died, and was fwallowed by his enemy. Thefe convulfions were probably confidered by old obfervers as the effect of the charming power of the ferpent, or of extraordinary fear; but they are a regular fymptom of the action of the poifon.

"Perhaps thefe experiments do not determine exactly the means which ferpents employ for feizing their prey, fo likely to efcape them by running or flying: but they feem fufficient to authorife us in rejecting all ideas of fafcination, or charm, of extraordinary terror or fuffocating vapour. On the latter point, I can ftate, that nine boiquiras were kept for three weeks in the fame box; when it was opened, at the end of this time, no particular odour was obferved." Daudin's Hift. Nat. des Reptiles, in the edition of Buffon, by Sonnini, v. 5. p. 55. et feq.

Thofe ferpents which have not this quick and effectual means of deftroying their prey by the poifonous apparatus, accomplifh their object in another manner. They throw themfelves on the animal which they attack, twine round his body and limbs, and exert, in this manner, a compreffive force capable of breaking the bones. When he is thus difabled from refiftance, they fmear him over with a mucous faliva, and fwallow him gradually in the way already defcribed. The enormous ferpents of Africa and America, thirty or forty feet long, are ftrong enough to attack and overcome the larger animals, and can then fwallow them entire. See the account of the boa aboma by Stedman, in his voyage to Surinam and Guiana; and of the boa conftrictor, in Adanfon's Voyage au Senegal, p. 152. et feq.

Proportion of the venomous to the harmlefs Serpents.—The number of ferpents poffeffing venomous fangs is more confiderable than has been generally fuppofed. "Ne telis horrentibus," fays Linnæus, "execrabili veneno nimium fævirent, decimam quamque tantum fpeciem armavit imperans, et verfipelles eos voluit, ut dubii omnes metuerentur ab omnibus." Yet Dr. Ruffel found feven venomous fpecies among forty-three, which he obferved; and the proportion of the venomous to the non-venomous kinds, among the ferpents defcribed by Daudin, in his Hiftory of Reptiles, is as 80 to 233. There are not more than 14 or 16 genera of ferpents indigenous in Europe, yet among thefe are five vipers. Of the fpecies defcribed by Daudin, 201 belonged to the ancient, and 112 to the new continent: the venomous kinds formed a fourth in the former, and a fifth in the latter.

Daudin gives the following lifts of the poifonous and harmlefs kinds.

Genera with poifonous fangs.	Genera without poifonous fangs.
1. Bungarus.	1. Boa.
2. Acanthurus?	2. Python.
3. Crotalus.	3. Corallus.
4. Scytale.	4. Hurriah.
5. Lachefis.	5. Coluber.
6. Cenchris.	6. Enhydrus.
7. Vipera.	7. Erpeton.
8. Platurus.	8. Eryx.
9. Langaha.	9. Anguis.
10. Clothonia.	10. Ophifaurus.
11. Hydrophis.	11. Pelamides.
	12. Acrochordus.
	13. Amphifbæna.
	14. Cæcilia.

See his Hift. Nat. des Reptiles, v. 5. p. 22.

The following is given by Humboldt as a comparative enumeration of the venomous fpecies in the old world, and in America.

In the old continent.	Species.	In the new continent.	Species.
Bungari	2	Bungarus	0
Crotalus	0	Crotali	7
Scytalæ	3	Scytalæ	2
Lachefis	0	Lachefes	2
Cenchris	0	Cenchris	1
Viperæ	44	Viperæ	10
Platuri	2	Platurus	0
Clothonia	1	Clothonia	0
Langaha	1	Langaha	0
Hydrophes	5	Hydrophis	0
	58		22

See the Recueil d'Obfervations de Zoologie et d'Anatomie comparée, v. 2. p. 5.

Horny Covering of the Jaws in the Chelonian Order.—This fubftance is fimilar in its nature to that which compofes the hollow horns of animals (fee HORN); and there is no effential difference between it and that of the bill in birds. (See BIRDS, in *Comparative Anatomy*.) As in birds, this horny covering is fpread over the oppofed furfaces of the two mandibles; but the organ fo covered is much lefs fufceptible of motion in the teftudines, as the upper mandible is always fixed in them. In general it is fenfibly fibrous in its texture, but fometimes it appears homogeneous. It is very hard, fo as to enable thefe animals to break fhells with facility. In this refpect, it is analogous to the horny bills of the birds of prey, and the refemblance is fo ftriking in one fpecies of turtle, that it has received the name of hawk's-bill. It is formed on a vafcular fubftance covering the bone, as is the cafe with the hollow horns and the bill of birds. The edges are fometimes fimple, fometimes ferrated, fometimes divided into large unequal teeth; the extremity is either entire and rounded, or grooved, or brought to a fharp point. The edge of the upper jaw is terminated by a thin fharp plate of horn, within which the lower paffes to fome height, being rather narrower in its tranfverfe meafurement: hence any fubftance may be cut by them as with fciffars, for the outer margin of the lower jaw is alfo brought to a fharp edge. Befides this fharp edge, there is a covering of fome breadth in the upper jaw, forming a ridge a ridge towards the anterior part, received into a correfponding concavity of the lower jaw.

Salivary Glands.—We have already obferved, that nothing deferving the name of maftication takes place in any reptile. They live on other animals, and almoft univerfally fwallow them whole. Some teitudines feed on fhell-fifh, and break the teftaceous coverings with their horny mandibles, but they do not *chew* the contained animals. The falivary apparatus muft, therefore, be very different from that of the mammalia.

Several reptiles, however, require the affiftance of fluids poured into the mouth for feizing and fwallowing their prey. Some, as the frog and cameleon, dart out the tongue, covered with a vifcid matter, upon infects, which are entangled in the flime, and thus captured. Serpents fpread a frothy flaver over the animals which they fwallow, to facilitate their paffage.

In fome reptiles the tongue is compofed, in great part, of a thick glandular mafs, formed of numerous fmall tubes united at their bafes, and feparating towards the furface of the tongue. They are fo many papillæ, giving a briftly appearance to the organ, or rendering it villous, when they are very fmall. The fides of the mafs are perforated by numerous pores, through which the fecreted fluid efcapes. This gland refts on the mufcles of the tongue, and follows the motions, which they communicate to the organ. The gland in queftion exifts in the chelonians; in the teftudo græca the ftructure juft defcribed is very evident. It exifts alfo in feveral faurians, as the flat-headed gecko (G. fimbriatus), the common iguana, and the Schneiderian fcink.

In the agame umbra (iguana umbra, Linn.) the gland is furmounted in front, inftead of papillæ, with tranfverfe plates clofely arranged. Thefe laminæ cover the whole furface in the cameleon.

The tongue feems to be covered by an analogous glandular fubftance in the batracians.

Where the tongue is fcaly, or fmooth, and covered with a fimple membrane, the place of this gland is fupplied by two others, elongated and glandular, fituated under the fkin, along the external furface of the branches of the lower jaw-bone, and pouring out their fluid at the outfide of the teeth of the fame jaw. In this direction they are in contact with the palatine membrane. Thefe glands are ftrongly marked in the tupinambes, the colubres, and the boas. In the amphifbænæ the glands are not fituated in the fame place, although they have the fame apparent ftructure. They lie immediately under the tongue, between the genio-gloffi and genio-hyoidei.

The conglomerate gland fecreting the poifonous fluid of the venomous ferpents is fpoken of in the defcription of the teeth.

The *os hyoides* varies in the different orders of reptiles, but it approximates in general very nearly to that of birds, from which it does not differ effentially in the faurian and ophidian orders. As in birds, its connections with the larynx are very inconfiderable: there is no mufcle paffing between them: a fimple membrane is the medium of union. They are, in fact, completely feparated in fome genera of faurians; as, for example, the cameleon: and the fame obfervation may be extended to all the ophidians which have a tongue included in a fheath. This circumftance completes the proof of what is rendered very probable by many other reafons, that the effential function of the os hyoides is to fupport the tongue, and affift its motions.

The form of the os hyoides varies much in the chelonians: fometimes the body is nearly fquare, thin, and flattened, then the pofterior cornua are ftraight, articulated to the pofterior angles of the body, feparating from each other as they pafs backwards, and having the larynx placed in their interval. The anterior cornua are confolidated to the body, a little behind the anterior angles, directed backwards, and curved upwards behind the occiput. In front the body is prolonged into a point, under the tongue, which it fupports. Such an os hyoides is feen in the teftudo græca. But in the matamata (teftudo fimbriata, Gmel.) the body is very folid, bony, and pyramidal, with the bafis turned forwards. The anterior cornua, forming angles towards the front, are articulated behind each angle terminating the bafis; while the pofterior, more flender, and bent like an arc, are fixed near each other to the apex of the pyramid.

Ufually the os hyoides confifts merely of cartilage in the faurians, as in moft other reptiles; its parts are generally flender, elongated, and confolidated with each other. Yet it preferves in the crocodile that flattened fhield-like figure, which we have defcribed it to poffefs in the chelonian order, and which we fhall difcover alfo in the batracians. There are only two cornua, articulated nearly in the middle of the fides of the cartilaginous plate. They feem formed of two portions united together, but diftinguifhed by a kind of angle projecting pofteriorly.

In the common iguana (I. delicatiffima, lacerta iguana, Linn.) the body may be confidered merely as the point of union of the feven cornua compofing the os hyoides An anterior one is continued under the tongue, without being fixed to it. The fix others are behind. The two loweft are the longeft; they are contiguous, flightly curved, and enter the goitre, without affording attachment to any mufcles or ligaments. The four others are true cornua of the hyoid cartilage. Two pafs firft forwards, but quickly bend backwards, and then upwards, to reach the occiput. The others are bent backwards and upwards, fo as to remain nearly parallel to thefe. They are analogous, in their form and ufe, to the correfponding parts in birds. The cornua belonging to the goitre are found alfo in the fcinks, agames, and dragons. In the dragon raye (draco lineatus) their extremity is attached to the large bag forming the goitre, and will draw it inwards, when the tongue paffes out of the mouth. Thefe cornua are not found in the other faurians. Sometimes there are only two hyoideal cornua, as in the gecko fimbriatus. They are always perfectly analogous to thofe of birds.

The os hyoides of the cameleon has four; of which two are ftraight and directed obliquely forwards. The two pofterior go behind the head. The body is prolonged to nearly the anterior third of the tongue, when that organ is in the ftate of repofe: it is cylindrical and flender in the whole of this part, which is between one and two inches long.

In the lizards and tupinambes, the number of cornua is alfo four. The anterior are formed of two pieces, confolidated, or moveable on each other, of which the firft is directed forwards, while the fecond turns backwards, and is curved towards the occiput.

In the ophidians, with a tongue inclofed in a fheath, the hyoid cartilage is compofed of two parallel threads, directed from before backwards, approximated to each other, feparated in their anterior half by the fheath of the tongue, and in the reft of their extent by the two hyogloffi. The two threads are united in front, nearly between the pofterior extremities of the branches of the jaw, being bent into a femicircle under the fheath of the tongue; from the convexity of their union a fhort point is continued under the fheath. In the other ophidians, as the amphifbænæ, &c. the

the hyoideal cartilage has a triangular figure: the two posterior angles are elongated to form the cornua.

The os hyoides forms a broad nearly square plate, immediately applied to the inferior parietes of the palate and back of the mouth, in all the batracians, except the salamanders. The anterior cornua go off towards the front from the anterior angles, separate more widely before they turn backwards, then are continued towards the angle of the jaw, and curved from below upwards, in front of this angle, to be fixed to the posterior part of the cranium. The posterior horns are straight, strong, bony, not consolidated with the square plate, but articulated to its posterior angles, and directed obliquely backwards and outwards. The larynx is placed between them. The hyoid cartilage of the salamanders has a triangular form: the cornua go off from the posterior angles, and ascend at the sides of the neck. Their posterior edge is consolidated to a thread of the same nature, bent in the form of a handle, and having its anterior extremity united to that of the opposite thread in the middle of the posterior concavity of the hyoid cartilage. On each side of the branches of this cartilage, towards the front, there is a broad cartilaginous plate, nearly parallel to them, and only joined by muscles which go from one to the other. It seems to hold the place of an anterior horn.

In the thirty-fourth plate of the fifth volume of the Leçons d'Anat. comparée, there are figures of the os hyoides of the iguana, the Nilotic crocodile, the Nilotic tupinambis, the lacerta agilis, the gecko fimbriatus, amphisbæna, another serpent, the testudo græca, the salamander and frog.

Muscles of the Os Hyoides. — In those saurians, which have a more or less protractile tongue, these muscles contribute greatly to its elongation, by carrying the bone forwards.

We find in reptiles; 1st, a muscle analogous to the mylohyoideus. It is composed, in the two first orders, of several portions; *viz.* an intermaxillary, fixed to the lower edge and internal surface of the branches of the lower jaw; a second very thick, ascending behind each angle of the jaw, upon the digastricus, and attached to the occiput; a third passing to different distances in the neck, fixed to the skin above, and embracing the neck like a girth. It is analogous to the cutaneus colli; and embraces the whole extent of the neck in the chelonians. In the common iguana the intermaxillary portion does not extend to the arch of the chin; and in the gecko there is only a thin aponeurosis reaching so far. But, in general, the mylo-hyoideus is fixed to the os hyoides in these two orders, which is not the case in the batracians; in which the muscle seems to exist merely for the purpose of filling the wide interval between the maxillary branches, and supporting and elevating the parts above it. Its fibres are directed transversely from one branch to the other; they are divided in several species by a median line, and attached to the internal surface of the maxillary branches, which enables them to elevate more advantageously the subjacent parts. In the rana ocellata the posterior edge is separated on each side, to ascend within the angle of the lower jaw as high as the palatine membrane.

2. The muscle analogous to the sterno-hyoideus is attached in the chelonians, between the two cornua of the same side, and to the posterior cornu; it descends along the neck, passes within the first bone of the shoulder, and is inserted on the inside of the neck of the second bone. It rests, in this course, against the sides of the œsophagus, and is strongly attached to the pharynx towards its anterior extremity.

The same muscle, in the saurians, is attached on the outside of the sternum, between the sterno-mastoidei, and is fixed to the posterior cornu of the hyoid cartilage. In the iguana, it is fixed to nearly the whole posterior edge of the first part of these cornua; in the gecko fimbriatus, to the middle of this edge. In the caïman, after touching the os hyoides, it is continued to the lower jaw, and inserted far back in its lower edge.

It is much elongated in the cameleon, and carried far backwards on the outside of the sternum, forming a point in the same direction. This muscle covers another, thinner and broader, but of the same length, equally contiguous to its fellow of the opposite side in the two posterior thirds, and inserted in the extremity of the posterior cornua of the os hyoides. It might be named sterno-ceratoïdeus. In the agame umbra (iguana umbra, Linn.), the same muscle extends equally backwards on the outside of the sternum. The sterno-hyoideus has two portions in the crocodiles, which are only separated beyond the sternum: the lower one is thinnest, and inserted in the edge of the hyoid plate; the outer, broader and thicker, reaches the posterior edge of the cornu, and after a slight tendinous intersection, which serves to attach it to this cornu, is continued in the same direction to the jaw, and forms the first layer of the cerato-maxillary muscle.

In the serpents, the place of the sterno-hyoideus is supplied by a costo-maxillary muscle, extending from the anterior ribs to the lower jaw. Its internal fibres go from the jaw and the ribs to the hyoid cartilage.

It is prolonged, in the batracians, except the salamanders, within the sternum, to the farthest end of this bone, where it is fixed; or it only reaches the middle of the sternum. Many of its fibres are expanded on the pleura. In front it is divided into several portions, inserted successively in the external edge of the hyoid plate. One of these goes as far as the anterior cornua, and is fixed to it by a slender tendon. In the salamanders, the sterno-hyoideus is continuous with the rectus abdominis, and partakes in its motions.

3. The omo-hyoideus does not exist in the ophidians.

In the chelonians it ends in the sheath of the mylo-hoideus, which incloses the extremities of the anterior cornua of the os hyoides. This muscle is very considerable in some saurians. In the gecko, for example, it is widened, to be inserted in the greatest part of the posterior cornua: it covers the greatest part of the sterno-hyoideus in front.

In the iguana it is contiguous to a muscle, which has the same direction: it is attached to the clavicle behind, and above the body of the hyoid cartilage in front. In the caïman it is also composed of two portions. The external, which is soon detached from the following, is fixed to the palatine membrane near the lower jaw. The internal is attached to the angle of the hyoideal cornu.

It is long and slender in the cameleon; it passes on the outside of the sterno-ceratoideus, and is fixed to the body of the os hyoides, on the outside of the sterno-hyoideus.

The omo-hyoideus of the frog is mentioned in the account of the muscles of the shoulder.

4. Muscle analogous to the stylo-hyoideus. This has only been noticed in the frogs and toads. It comes from the back of the head, behind the ear, where it is attached at the side of a muscle analogous to the sterno-mastoideus. It is divided into two portions in the rana ocellata, and into three in the common frog: they are all attached to the posterior cornu.

5. The genio-hyoideus. The chelonians have only one, the tendon of which is fixed to the arch of the chin: the two fleshy portions separate as they go backwards, and are fixed to the basis of the posterior hyoideal cornua. In several saurians the structure is nearly the same; as in the common iguana, and the caïman, for example. It consists of two portions

portions in the cameleon; an internal long and flender one, inferted in the body of the os hyoides; an external broader and ftronger, contiguous to the former, and attached to the pofterior cornua in their whole length: it has an attachment alfo to the anterior cornua.

In the ophidians the genio-hyoidei are continuous behind with the cofto-hyoidei. They are only obferved in thofe whofe tongue is not inclofed in a fheath.

The genio-hyoidei are divided behind into two portions, in the batracians. The external and fhorteft is inferted on the fide of the hyoideal plate above its edge; the internal is prolonged on the pofterior cornua, and furnifhes a fheath to the hyogloffus. The fterno-hyoideus penetrates between thefe two portions, to be fixed to the plate.

6. The cerato-maxillary mufcles. Thefe are analogous in their attachments and ufe to the conical mufcles of the os hyoides in birds: they only differ from them in not being turned round the cornua. They are found in the three firft orders, but do not exift in the batracians. They arife from the pofterior third of the internal furface of the branches of the lower jaw, and proceed backwards and inwards to the pofterior cornua of the os hyoides. There are two on each fide, attached to the four cornua, in the iguana. This animal has, moreover, a tranfverfe mufcle of the cornua, the fibres of which go obliquely outwards from the anterior to the pofterior cornu of the fame fide.

In the agame umbra the laft mufcle is long and flender, continued from the extremity of the pofterior cornu to the angle of the anterior.

In the chelonians, the cerato-maxillary are inferted into the extremities of the anterior cornua.

The *tongue* varies confiderably in this clafs of animals: it is employed, in many inftances, as the means of procuring their food, by thofe reptiles which feed on infects. But as none of this clafs mafticate their aliment, or fwallow it like the mammalia, the form of the organ is very different from that which it exhibits in the mammiferous animals.

The chelonians have a fmall pyramidal tongue, with the bafis turned backwards, the apex forwards.

A large part of the faurians and ophidians have a tongue capable of confiderable elongation. The moft remarkable example occurs in the cameleon, where it is not larger than a quill, but five or fix inches long: it is expanded at its extremity, which is covered with a vifcous fecretion. This weapon lies commonly in a fheath at the bottom of the mouth, contracted to the length of about an inch, or lefs. The animal can dart it out at pleafure, when the vifcous fluid at its end entangles the prey, which is taken into the mouth with great celerity. "Quand les caméléons veulent manger," fays Belon, "ils tirent leur langue, quafi d'un demipied, ronde comme la langue d'un oifeau nommé picvérd, femblable a un verre de terre; et a l'extremité d'icelle ont un gros nœud fpongieux, tenant comme glu, duquel ils attachent les infectes, favoir eft fauterelles, chenilles & mouches, et les attirent en la gueule. Ils pouffent hors leur langue, la dardant de roideur auffi vîtement qu'un arbalête ou un arc fait le traict." Pierre Belon, Obfervations, &c. liv. ii. ch. 34.

In the common lizards, the tupinambes, &c. the tongue is fmooth, extenfile, and terminated by two long flexible points, although femi-cartilaginous and nearly horny: it refembles perfectly that of the ophidians, excepting the anguis and amphifbæna, and perhaps alfo the cæcilia, which have it flat, and merely forked at the end, without the power of elongating it.

In moft of the ferpents, the tongue, when contracted, is contained almoft entirely in a membranous fheath. The mechanifm belonging to thefe projectile tongues partakes both of that which is found in fome mammalia, as the echidna and the ant-eaters, and of that of birds. (See MAMMALIA and BIRDS, in *Comparative Anatomy*.) It depends on mufcles acting on the os hyoides, and alfo on the mufcles of the tongue.

The ftellios and iguanas have a flefhy tongue, villous on its furface, and poffeffing about the fame mobility as that of the mammalia. In the fcinks and geckos it differs from the former only in being fiffured at the end; and it refembles, in this refpect, that of the angues, between which and the fcinks there is in all points much analogy.

The tongue of the batracians is not only different from that of other reptiles, but alfo from that of other animals. It is flefhy, of a flattened figure, fmooth, and covered, in all of the frog and toad kind, with a tenacious mucus. It is villous in the falamanders, and covered with very long papillæ in the horned frog (bufo cornutus, rana cornuta, Linn.). The great peculiarity of the tongue is its being attached by the bafis to the front of the mouth, to the fymphyfis of the lower jaw. This is its thickeft part: it is continued backwards in a thinner form, fo as to end in two loofe and flat portions, reprefenting the apex, and lying in the back of the mouth. This loofe part, ordinarily turned back towards the throat, is projected from the mouth, covered by its vifcous fecretion, upon the fmall infects which the animal feeds on, and which are thus entangled and fwallowed.

Mufcles of the Tongue.—They poffefs nothing peculiar in the chelonian reptiles, which have not an extenfile tongue: they confift merely of two pairs. The hyogloffi come from the anterior half of the pofterior cornua, and penetrate into the tongue at the fides of the bafis.

The genio-gloffi are very ftrong and broad in the vertical direction: they come from the front of the lower jaw, and enter the tongue more outwards and forwards than the preceding, with which their fibres are interwoven. The apex of the hyoid cartilage penetrates between them: they are alfo feparated by a fmall cylindrical cartilage, to which each mufcle is fixed; which is prolonged behind under the body of the hyoid cartilage, extending in front to the apex of the tongue.

The faurians have in general three pairs of mufcles going to the tongue from the os hyoides or the arch of the chin, and a proper mufcle attached to the organ only.

1. The hyogloffus comes from the cornua of the hyoid cartilage. In the common iguana it is attached to the pofterior cornua, oppofite the omohyoideus. In the gecko fimbriatus it is fixed to the middle of the cornua, at the fide and within the cerato-maxillaris: it forms, with the ftraight genio-gloffus, the bafis of the tongue, and mixes its fibres with thofe of the proper mufcle. The hyogloffus is long and cylindrical in the lizards and tupinambis: it comes from the extremity of the pofterior cornua, approaches the oppofite mufcle as it advances forwards, becomes contiguous to it at the bafis of the organ, towards the extremity of which it terminates in forming the two portions of cylinders, of which this tongue confifts. In the cameleon it is fixed to the whole anterior edge of the pofterior cornua, and is very thick at that part. Beyond the angle formed by the two cornua of the fame fide, it is curved and continued directly forwards. The fafciculi of fibres, of which it confifts, are inferted in the pofterior half of the fheath of the tongue, which it ferves to draw backwards.

2. The ftraight genio-gloffi come from the inferior edge of the arch of the chin, and are continued to the bafis of

of the tongue; where they meet the hyogloſſi, with which their fibres are interwoven.

3. The tranſverſe genio-gloſſi are attached to the arch of the chin, and to the anterior part of the inferior maxillary branches, on the outſide of the preceding. Inſtead of being narrow and elongated, they are broad and ſhort. Their fibres paſs obliquely from without, inwards and backwards upon the membrane of the mouth, as far as the ſides of the tongue; which they will draw outwards and forwards. The two laſt pairs of muſcles do not exiſt in the cameleon.

4. The proper muſcle is found in thoſe ſaurians only, whoſe tongue admits of elongation. It is compoſed, in general, of annular fibres. In the gecko fimbriatus, which has a broad tongue, this muſcle is divided in front into ſix or eight ſmall portions, which are united into two towards the middle third of the tongue, and then into one on each ſide, which form the two pieces of the baſis of the tongue.

In the cameleon the annular muſcle is very thick, and forms a fleſhy cylinder ſurrounding the anterior three-fourths of that part of the os hyoides which penetrates into the tongue. Towards the front it is divided on the ſides into two portions, a ſuperior and an inferior; the latter is folded back towards the ſheath of the tongue, to which it adheres. There is, moreover, a muſcle proper to this ſheath, which may be called the retractor muſcle. It comes from below the glandular part, and is continued, on each ſide, as far as the part that is puckered up. When the hyogloſſus throws this latter part into wrinkles, and ſhortens it, and the os hyoides is carried backwards by the ſterno-hyoidei and ceratoidei, the retractor muſcle cauſes the end of the ſheath to remain applied to the extremity of the annular muſcle which recedes, becauſe then its poſterior attachments are the moſt fixed: on the contrary, when the extremity of the os hyoides and the annular muſcle puſh the ſheath forwards, the anterior attachments have a point d'appui; the poſterior portions of the retractor draw forwards the ſheath, and unfold it.

By putting together what we have ſaid concerning the os hyoides and its muſcles in the cameleon, in a former part of this article, and what we have juſt ſaid of the muſcles of its tongue, it will be eaſy to underſtand how this organ can be elongated, and withdrawn into the mouth. The firſt office is performed by the annular muſcle, with the cerato-maxillary, and the genio-hyoidei. The ſterno-ceratoidei and hyoidei carry backwards the os hyoides, at the ſame time that the hyogloſſus ſhortens the ſheath and puckers it up.

In moſt of the ophidians the tongue is incloſed in a membranous ſheath, which opens behind the interval of the branches of the lower jaw, and is continued backwards between thoſe of the hyoid cartilage, under the trachea. It is lined internally by the membrane of the mouth. This ſheath is carried forwards by a pair of muſcles analogous to the genio-gloſſi. They derive their origin by two portions, one of which comes from between the two branches of the lower jaw, the other from their extremity; they come together and are fixed to the ſides of the ſheath to its moſt diſtant extremity. The hyogloſſi are two elongated muſcles, contiguous, and even united together by fine cellular laminæ. They exactly fill the interval of the cornua of the hyoid cartilage, and are even doubled backwards round their extremity. Theſe muſcles go to the baſis of the ſheath, and draw it backwards, when it has been carried forwards by the two firſt pairs.

The proper muſcle is formed of two cylinders, firſt lying together, and ſeparated towards the anterior third of the tongue, for the two portions of which its apex conſiſts; here they become conſiderably diminiſhed, and are reduced to a mere thread at the end.

This ſimple apparatus, combined with that of the os hyoides and its muſcles, gives to the tongue of the ſerpent that wonderfully quick power of extenſion and retraction. Carried forwards by the genio-vaginal muſcles, brandiſhed by its proper muſcles, it re-enters the ſheath in conſequence of the elaſticity of the hyoideal cornua, which tend to reſtore themſelves, and of the action of the hyogloſſi. One or other of theſe actions is aſſiſted by the coſto-maxillary muſcles, according as the portion analogous to the ſterno-hyoideus, or that which correſponds to the cerato-maxillary, contracts. The extenſion of the tongue out of the mouth is ſo much the greater, becauſe it is effected through an orifice near the extremity of the ſnout, and becauſe its baſis may be brought near to this part.

In the amphiſbænæ, which have a flattened tongue, not incloſed in a ſheath, nor ſuſceptible of extenſive motion, there are, 1ſt, two genio-gloſſi attached to the arch of the lower jaw, more internally than the genio-hyoidei; 2dly, two hyogloſſi; and 3dly, two cerato-gloſſi, which preſent nothing worthy of particular notice.

The tongue of the batracians, as we have already deſcribed, is fixed in front to the arch of the lower jaw, and free behind. In paſſing out of the mouth, and going back again, it turns upon the fixed point of its attachment to the jaw. Two pairs of muſcles, the genio-gloſſi, and the hyogloſſi, execute theſe motions. 1. The hyogloſſi form, in the rana ocellata, two cylindrical maſſes, lying on, and attached to, the poſterior cornua. They ſoon unite into a ſingle maſs, which reſts on the hyoideal plate, and penetrates the tongue in front of this plate, expanding into ſmall faſciculi, which reach to the looſe edge of the organ. 2. The genio-gloſſi form at firſt two ſmall ſpherical maſſes, placed at the arch of the chin on the ſmall tranſverſe muſcle; they are ſubſequently elongated into two contiguous cylinders, of which the fibrous faſciculi ſeparate from each other, decuſſate with thoſe of the preceding muſcle, and go to the looſe edge of the tongue. While the tongue is in the mouth, the hyogloſſus is folded on itſelf, and the genio-gloſſus is ſtraight. The latter muſcle is folded, and the former ſtraight, when the tongue has been projected. In the common frog, theſe two pairs of muſcles are not ſo minutely divided in the tongue, and the genio-gloſſi do not form ſpherical maſſes towards the arch of the chin: in other reſpects they are ſimilar.

Tongue of the Crocodile.—Humboldt has obſerved a peculiar mechaniſm in the tongue of this animal, bearing an evident relation to its wants and habits, of which the following is a deſcription in his own words.

"From the moſt ancient times diſputes have exiſted concerning the tongue of the crocodile; ſome naturaliſts pretended that it was entirely wanting, others affirmed that it was very ſhort, and placed at the entrance of the œſophagus. According as one or the other of theſe opinions prevailed, the ſculptors and antiquaries of Rome amuſed themſelves with deſtroying or reſtoring the tongues of their crocodiles. When we examine attentively the os hyoides of this animal, we find that it is in conſequence of its form and ſmall ſize that a part or rather a fold of the tongue has been confounded with the whole organ. There is in this animal a peculiar mechaniſm, by which a valve is formed, interrupting the communication between the mouth and throat. When the crocodile appears motionleſs on the bank of the river, with the jaws opened at an angle of

95°,

95°, the whole mouth appears yellow: the valve is elevated, and the opening of the fauces is not feen. If we furprife him, the valve is generally depreffed; and if a perfon runs the rifk of approaching fufficiently, a round body of a beautiful red colour, which is the opening of the glottis, may be perceived. This valve enables the crocodile to feize his prey under water without running the rifk of being inundated by the great quantity of fluid that would pafs into the œfophagus. When he fwallows, the valve muft be depreffed, and the animal on dry ground. The os hyoides of the crocodile of the Orinoco is a membranous fpatula, broad, concave, and terminated by two fhort horns. The os hyoides of the Egyptian crocodile, as delineated by Mr. Duverney, is altogether different from that of the South American animal; another proof of the diftinction between the crocodiles of the old and new continent. In an animal of eighteen feet, the tongue is twenty-five inches: it is yellow, flefhy, and covers the whole jaw; but it is attached on all fides, fo that the os hyoides cannot elevate it to the end. The anterior or fpatula-fhaped portion of this bone enters the membranous fubftance of the tongue, which it can elevate at a right angle. As the fides and extremity of the organ are fixed, this motion of the bone can only carry with it the membranous part of the tongue, which forms the fold prefenting itfelf like an elevated valve. The os hyoides is depreffed, and the valve immediately difappears. Three conditions are neceffary to the execution of this mechanifm, a tongue attached to the lower jaw; a ductile and flexible membrane covering it; and an os hyoides broad in front. The yellow fubftance in the anterior part of the mouth belongs to the tongue as well as the fold covering the entrance of the œfophagus. Humboldt found that the tongue fwelled very much, when fubjected to Galvanic influence, by means of zinc and filver. See Recueil d'Obfervations d'Anatomie comparée et Zoologie, faites dans le Voyage de Humboldt et Bonpland, t. 1. pag. 9. pl. 4.

Geoffroy gives a fimilar defcription of the tongue, os hyoides, and their mechanifm, in the Nilotic crocodile. He defcribes it as a yellowifh, fhagreened fkin, exactly like the fubftance of the palate, pierced by numerous fmall holes, the excretory ducts of the glands fituated on its upper furface, and adhering on all fides to the branches of the lower jaw. He fpeaks of the broad anterior part of the os hyoides forming, by its elevation, a veil, which covers all the back of the mouth. Thus, the animal can remain under water with the jaws open, and receive air through the noftrils, the only part above the furface, without the water entering the throat or trachea. Annales du Mufeum, vol. ii. p. 42, et feq.

Epiglottis.—In moft reptiles the opening of the glottis is neither covered by a valve, as in the mammalia, nor armed with papillæ, as in birds. Yet a kind of epiglottis may be obferved in the common iguana, and in the Schneiderian fcink. There is a rudiment in the crocodiles; it does not appear in feveral other animals of the fame order, nor in the chelonian, ophidian, and batracian reptiles. The cylindrical larynx of the dragon, and its fimple opening behind the root of the tongue, are very well reprefented in Blumenbach's Abbildungen Natur-Hiftorifcher gegenftände, N° 98. Is the abfence of the epiglottis connected with the peculiar modification which refpiration undergoes in this clafs? or with their deglutition? On the former point we may obferve, that, as they breathe only at confiderable intervals, there is no danger of the glottis being opened during fwallowing, and its edges may confequently be kept clofely approximated. Again, as they fwallow their food whole, it is not likely to pafs into the larynx.

Fauces.—The openings of the noftrils are fituated very forwards in reptiles, and are not clofed by any moveable curtain, as in the mammalia. A kind of immoveable valve, attached to the anterior edge of the opening, and leaving the orifice free behind, may be feen in the gecko fimbriatus.

There is fomething analogous to the velum palati in the crocodile. The noftrils open far back, contrary to what we have mentioned concerning other reptiles. They form a round aperture in the moft diftant part of the arch of the palate. The membrane lining this concavity forms a loofe production a little in front of the opening in queftion, which defcends on the fides, growing a little broader, until it meets another elevation behind the bafis of the tongue. Thefe form together, by their loofe edge, the ifthmus faucium, or entrance of the throat. The firft affords fome protection to the opening of the noftrils, but cannot entirely clofe it; the latter contributes, with the rudiment of the epiglottis already mentioned, to cover the glottis.

The entrance of the throat is large in all reptiles, and capable, in many, of ftill greater fize, by the expanfion of the lower jaws. There is nothing deferving the name of ifthmus. They fwallow entire animals, which cannot pafs into the noftrils, and hence do not require a velum palati.

Pharynx.—As the noftrils open forwards in reptiles, the pharynx has not the fame relation to the nafal cavity, as in the mammalia and birds. The mouth and larynx communicate with it, and there is ufually a large aperture correfponding to the Euftachian tube.

The pharynx can hardly be diftinguifhed from the commencement of the œfophagus in reptiles. Their diameter is ufually the fame; and there is abfolutely no difference in the afpect of the membrane forming their internal parietes. It prefents a great number of longitudinal folds, which are effaced when a prey of large fize is fwallowed. There is no exterior mufcle enveloping the entrance of the canal.

Deglutition may be affifted, in the chelonians, by the action of the fterno-thyroidei, which reft on the œfophagus in the whole length of the neck; and even adhere in front to its parietes, and to the part which may be regarded as belonging to the pharynx. The os hyoides may alfo contribute to deglutition, by means of the mufcles which elevate it.

This office is particularly evident in the batracians, and efpecially in the frogs and toads. The hyoideal plate, which fupports in thefe animals the extenfive parietes of the back of the mouth and palate, is put in motion by the mylohyoideus and the mufcles analogous to the ftylo-hyoidei, only for the purpofe of elevating thefe parietes, and applying them to the concavity of the palate. There is alfo another mufcle coming from the upper and back part of the head, in front of that which correfponds to the ftylo-hyoideus; it is narrow at its origin, but expands as it paffes forwards and downwards, and as it covers that part of the throat which is prominent behind. It is continued to the edge of the hyoideal plate, in which it is inferted, its fibres adhering alfo to the membrane of the throat, on which they lie. Their action will elevate the hyoideal plate, and apply the membrane which they cover to the oppofite furface of the cavity.

The longitudinal fibres, belonging both to the pharynx and œfophagus, are more or lefs ftrongly marked.

Œfophagus and Stomach.—The former tube does not prefent thofe dilatations which we notice in birds: it retains nearly an uniform diameter throughout, or the change, if any, is gradual. But this diameter is, in moft cafes, much more confiderable, in comparifon with that of the ftomach, than in the two preceding claffes. Under certain circumftances, indeed, the œfophagus is larger than the ftomach in in the ophidians; for example, when the latter is not diſtended with food, becauſe its parietes contract ſooner after enlargement than thoſe of the œſophagus. The membranes are the ſame in both, and, when the tube increaſes in ſize inſenſibly to the ſtomach, it is often very difficult to aſſign the limits of the two parts, and conſequently the ſituation of the cardia. The ſtomach is generally without any cul-de-ſac, oval and elongated: its parietes uſually thin. The muſcular coat is then hardly perceptible, at leaſt in ſome part of its extent, and the cellular is confounded with the mucous or internal. The pylorus is uſually without any valve; it is marked by a ſimple contraction, by the greater thickneſs of the parietes of the ſtomach, and by the different ſtructure of the inteſtinal membranes.

In the turtle, the internal ſurface of the œſophagus is beſet with long, hard, conical papillæ, of which the points are directed backwards, with the effect, apparently, of preventing the return towards the mouth of the matters ſwallowed by the animal. Such, at leaſt, is the notion generally entertained of the end or purpoſe of this ſtructure. But the abſence of ſuch proviſion in all other animals, where the neceſſity ſeems equally to exiſt, cannot but render us ſceptical on the ſubject, more particularly as we know no facts concerning the nature of the food, the mode of its deglutition, nor any peculiar modification of ſurrounding or connected organs, to which this ſingular ſtructure might be ſuppoſed to bear ſome relation. The ſtomach is gradually diminiſhed in ſize from the cardia to the pylorus: it is bent on itſelf, and the portion beyond the curvature is thicker than the reſt, in conſequence of the muſcular fibres being more copious. The internal coat has longitudinal folds in this part, but hardly any in the other. The ſituation of the cardia is well marked, and the œſophagus is diſtinguiſhed from the ſtomach by the ſudden dilatation of the latter. The pylorus has no valve.

Among the ſaurians, the crocodile has a peculiarly ſhaped ſtomach; it is very diſtinct from the œſophagus by its globular figure. Near the inſertion of this canal there is ſeparated from it below a ſmall cul-de-ſac, opening into the inteſtine by a very ſmall orifice, and having its cavity ſeparated from the great ſac of the ſtomach by a kind of ſtrait. Conſequently the general cavity of the ſtomach is a large cul-de-ſac, of which the parietes are very thick. The internal membrane forms conſiderable plaits arranged in a ſerpentine form, like the convolutions of the brain. The cellular coat, which is not very diſtinct from the mucous in the œſophagus, becomes more ſo in the ſtomach. The muſcular nearly equals the two others in thickneſs; the coats are altogether much thinner in the ſmall cul-de-ſac.

In the other ſaurians there is no cul-de-ſac. The ſtomach is oval and very elongated in the iguana, without curvature; the œſophagus dilates gradually to form it. The only mark that can guide us in determining the ſituation of the cardia is, the ceſſation of the longitudinal folds of the internal œſophageal membrane. The ſtomach is ſuddenly contracted, and bent a little before its termination at the pylorus. Its parietes become thick and opaque at ſome lines from this aperture, from an increaſe of the muſcular fibres, of which the tranſverſe are ſtrongly marked. The internal coat forms no fold; there is no valve at the pylorus, which is very ſmall.

In the tupinambis monitor the ſtomach forms a long tube, bent into almoſt a complete circle.

In the Schneiderian ſcink we again meet with the ſame elongated form, tranſparent parietes, and difficulty of diſtinguiſhing the ſtomach from the œſophagus, except by the longitudinal folds of its inner membrane, and the thickneſs of its muſcular coat. But the poſterior part of the ſtomach contracts ſuddenly, is bent towards the right, and a little elongated in this direction before it terminates. The parietes of the latter portion are more thick and opaque, and its internal membrane is folded longitudinally.

The ſtomach begins by a ſmall dilatation in the cameleon, then it aſſumes a cylindrical and elongated form, and is bent on itſelf; it is conſiderably contracted before it terminates, and forms a ſmall cylindrical canal, of which the internal membrane is folded longitudinally. The muſcular coat is thicker in this contracted part than elſewhere. It forms a prominent ring at the pylorus.

In the dragon the ſtomach is ſhaped like a pear, of which the large end correſponds to the cardia; it has no curvature; its parietes are tranſparent; they become thicker and opaque near the pylorus; and theſe characters are the only circumſtance, by which we can diſtinguiſh it from the beginning of the inteſtinal canal, which has thin and tranſparent coats.

The ſtomach is alſo pear-ſhaped in the gecko; the œſophagus makes a curve before it ends, and is inſerted at one ſide of the baſis. It is narrow, with thick coats, a ſtrong muſcular covering, and broad longitudinal folds of the internal or mucous coat. The ſides of the organ are thicker at its extremities; and the pyloric end is a little bent. The internal membrane is ſmooth.

In the ophidian order the ſtomach is ſhaped like an inteſtine, hardly larger than the œſophagus, and without curvature. The internal membrane is folded longitudinally. When the ſtomach is empty, theſe folds are thicker than thoſe of the œſophagus, which are not always obſerved.

The œſophagus of a ſnake, examined by Spallanzani, formed a cylindrical tube like an inteſtine, for about nine inches: it then became gradually narrower, ſo as to conſtitute a funnel of the length of four inches and a half. This funnel was the true ſtomach. The ſides of the ſtomach were thicker than thoſe of the œſophagus: no glands or follicles could be ſeen in the latter; but the ſtomach was abundantly ſupplied with them throughout its whole length; they diſcharge part of their liquor on being preſſed, and the internal coat is moiſtened with it. Diſſertations relative to the Natural Hiſtory of Animals and Vegetables, v. 1. p. 112 and 113.

In frogs and toads the ſtomach is ſhaped nearly as in the chelonian reptiles. At firſt conſiderably dilated in compariſon with the œſophagus, it is gradually contracted, then curved ſo as to form an inteſtine-like canal, with thick coats, ending at the pylorus.

It is ſlightly curved only near its poſterior extremity in the ſalamanders. Its figure is elongated and not much ſwoln; the parietes thick; and the internal membrane exhibits ſmall rugæ. There is a fold near the pylorus, in the ſituation of the curvature. Figures of the ſtomach and inteſtines of various reptiles are given in Cuvier's Leçons, pl. 41.

Inteſtinal Canal.—Its length, in proportion to that of the body, is greateſt in the mammalia, and diminiſhes ſucceſſively in birds, reptiles, and fiſhes. In reptiles it is often hardly twice the length of the body, taken from the extremity of the ſnout to the anus. But tadpoles exhibit in this reſpect a remarkable peculiarity. Their inteſtinal canal is nearly ten times as long as the ſpace between the ſnout and anus, while in the frog it is not more than twice the length of the correſponding ſpace. Other important differences, which will be noticed ſubſequently, exiſt in the two caſes. This ſhortneſs of the alimentary canal correſponds to the nature of the food in reptiles, which is derived from the animal kingdom.

The

The following table of the length of the inteſtinal canal in various reptiles, is taken from the third volume of Cuvier's Leçons d'Anatomie comparée, p. 457.

Names.	Length of the body.	Length of the ſmall inteſtine.	Length of the large inteſtine.	Length of the whole canal.	Proportion to the length of the body.

* In a common ſnake of four feet in length, Blumenbach found the inteſtinal canal about three feet, nearly ſtraight, or at leaſt very ſlightly undulated: its proportional length was therefore different from that expreſſed in the table. Specimen Phyſiol. Comp. p. 30.

The inteſtinal canal of reptiles has in general no appendix to mark its diviſion into large and ſmall inteſtines; this diviſion exiſts neverthelefs in moſt of them. All the chelonians, moſt of the ſaurians, the ophidians, and the batracians, with the exception of the ſiren lacertina, have a long and ſlender inteſtine, inſerted into a large and ſhort inteſtine, and commonly prolonged into the cavity, ſo as to form a circular margin of a valve-like form. The ſides of the large inteſtine are almoſt always thicker and ſtronger than thoſe of the ſmall. The membranes differ too; the muſcular in reſpect to its longitudinal fibres, and the internal in its folds. The iguana is the only animal of this claſs, in which a true cæcum has been noticed.

Of the Inteſtinal Canal.—All reptiles have the inteſtinal canal very ſhort, but not of the ſame diameter in its whole length. In the firſt and moſt conſiderable portion, the capacity is much inferior to that which it is found to poſſeſs near its termination; ſo that it may be divided, as in the mammalia, into ſmall and large inteſtines. A circular valve is moſt frequently found ſeparating the two diviſions; it is formed by a prolongation of the ſmall inteſtine, which becomes dilated, and ſometimes is extended into a kind of ſac, projecting more or leſs into the cavity of the large inteſtine, and rendering the parietes double at that part. It is thus found in the Schneiderian ſcink.

In tortoiſes, the diameter of the ſmall inteſtine gradually diminiſhes from the pylorus to the point of its inſertion into the large: the area of which is four times greater than that of the ſmall, and its parietes have the ſame ſtructure as in the other reptiles. The cavity is regular throughout, there being no partial dilatations or ſacculi. The internal membrane has folds, more or leſs broad, and of a membranous ſtructure, in different ſpecies, ſometimes connected in a reticular form at the commencement of the ſmall inteſtine, having a longitudinal and parallel direction in the reſt of its extent, and arranged more or leſs irregularly in the large. The large inteſtine proceeds in a ſtraight direction to the anus, whilſt the ſmall makes many irregular turns in its courſe.

Blumenbach found the inteſtinal canal of the hawk's-bill turtle (teſtudo caretta) five times as long as the whole animal. The ſmall inteſtine, as it is called, was larger than the ſhort portion of the large inteſtine; the whole internal ſurface was covered internally with an abundance of mucus. Syſt. of Compar. Anat. p. 173.

The internal coat of the inteſtine of the turtle is covered with innumerable thin longitudinal proceſſes, lying cloſe together, and increaſing the ſurface of the gut to a vaſt extent. They are moſt numerous in the upper part of the canal, and gradually diminiſh in number, until they ceaſe altogether, below. In the latter reſpect they reſemble the valvulæ conniventes of man, and the villi of all animals. For theſe ſtructures are always moſt diſtinct at the commencement of the canal, where abſorption goes on to the greateſt extent. The alimentary matter is deprived more and more of its nutritious parts, as it deſcends in the inteſtine; and hence a leſs extenſive abſorbing ſurface is ſufficient, in the lower part of the canal, for taking up the remains of really nutritious particles. Yet Blumenbach ſays that he found theſe folds ſo numerous in the rectum of the hawk's-bill turtle, that a ſection of the gut reſembled a broad radiated band. Lib. cit. p. 173, note.

In the crocodile of the Nile, the ſmall inteſtine may be diſtinguiſhed into two portions, the one more capacious, having thinner coats, and making four turns in ſuch a manner as to form four permanent angles; the other, more contracted and having thicker parietes, incloſes between its internal and muſcular coats a layer of glandular ſubſtance, ſemi-tranſparent, of a grey colour and pulpy conſiſtence. In the internal membrane lining the glandular ſubſtance, there are ſeen longitudinal folds arranged in a zigzag form, and connected together laterally, by ſmaller folds, ſo as to form a reticular ſurface. In the firſt portion of the ſmall inteſtine, where the glandular ſubſtance is not manifeſt, the folds arranged in a zigzag form are replaced by fine villous eminences. Near the termination of the ſmall inteſtine there are only ſeen ſome waving folds, connected by a few, proceeding tranſverſely. In the large inteſtine, the folds are arranged irregularly, forming a velvet-like ſurface.

The form of the rectum (under which term is included the large inteſtine of fiſhes and reptiles) is cylindrical in the crocodile of the Nile; and the ſmall inteſtine, where inſerted into it, is nearly of equal diameter. In the gavial

(Gangetic

(Gangetic crocodile), the large inteftine has a pyriform figure, the termination of the fmall being inferted into its broadeft part.

In the lizards, the rectum is cylindrical, and much broader than the fmall inteftine which is inferted into it; the latter, after having turned forwards from the pylorus, is folded backwards, and proceeds in a tortuous direction as far as the rectum, which purfues a ftraight courfe to the anus. The parietes of the inteftinal canal are thin and tranfparent; the internal membrane has folds arranged in a zigzag form.

In the cameleon, the coats of the inteftine have the fame ftructure; the capacity of the fmall is not much inferior to that of the ftomach and large inteftine, in the greateft part of its extent; but it becomes much contracted a little before its infertion into the latter. There is no valve indicating the feparation between the different portions; the internal membrane has waving folds, the loofe edges of which have a fringed appearance; they are directed longitudinally, and contracting as they approach the rectum, difappear at fome diftance from that inteftine, where the internal membrane becomes fmooth and without any folds. The mufcular coat is thicker in the rectum than in the fmall inteftine, where it is indiftinct. The cellular coat is not manifeft.

In the dragon, the inteftinal canal forms two turns and a half before it arrives at the anus; the commencement is diftinguifhed only by the different appearance of its coats, which are much thinner than thofe of the ftomach.

In the iguana, the parietes of the inteftinal canal are thin and tranfparent, gradually contracting from the pylorus to the infertion of the fmall inteftine into the rectum; the latter is of an elongated form, but contracted at one part, by which it becomes divided into two portions almoft of a cylindrical fhape. The internal membrane has fome folds directed longitudinally in the fmall inteftine. In the common iguana, which has the inteftinal canal long and very capacious, there is a true cæcum, diftinguifhable from the large inteftine by the greater thicknefs of its coats, and by a partition feparating their cavities, fo that it is through a very narrow orifice that the fecal matter paffes from the cæcum into the fucceeding part of the large inteftine. The infertion of the fmall into the former takes place near its middle. The coats of the cæcum have in fome degree a facculated form. The internal furface is fmooth and without folds. In the large inteftine the internal membrane has the fame ftructure, except at the commencement, where there are found about fix tranfverfe valves, which do not extend around the whole tube of the inteftine. In the fmall inteftine there are longitudinal folds. The pouch formed by the cæcum is about three-fourths of an inch in length, and twice as much in breadth.

In the gecko à gouttelettes the parietes of the inteftine are alfo tranfparent, the fmall has but little capacity, but is unequal at different parts; it is inferted into the centre of the firft portion of the large inteftine, which is of a globular form; and is feparated, by a contraction in its coats, from the fecond portion, which is elongated and oval, the fmall extremity correfponding to the anus. In the Schneiderian fcink the thin and tender coats of the inteftinal canal are much dilated at the commencement of the fmall inteftine, and contracted at the part where it is introduced into the large. We have already mentioned that it is dilated into the form of a bladder, and enveloped by the firft portion of the large inteftine, fimilarly dilated. The excrements, which pafs through the fmall aperture in the veficular dilatation of the fmall inteftine, find their way partly into the interval between the latter and the internal furface of the large. Beyond the firft portion the rectum becomes cylindrical. The fmall inteftine is divided into many pouches by contractions which pretty nearly correfpond to its different turns.

In the ophidian order the inteftinal canal purfues a ferpentine direction as far as the rectum, and preferves nearly the fame diameter throughout, dilating but little in the large inteftine. In the fmall, the internal membrane forms broad longitudinal layers, folded in the manner of ruffles; it is rugous, and in the rectum forms thick, irregular folds, which are continued to the anus. In the coluber natrix, according to Blumenbach, the whole length of the inteftinal canal does not equal that of the animal. The fmall inteftine forms a very confiderable valve at its entrance into the large. Lib. cit. p. 174.

In the falamanders, the fmall inteftine is very narrow in comparifon with the rectum, where the internal membrane forms thick and fimbriated folds. In toads and frogs, we find a nearly analogous conformation and ftructure, there being only a flight variation in the form of the rectum, which is more or lefs of a conical or pyriform fhape, as in many frogs, or cylindrical, as in toads. But in the tadpoles of both, the inteftinal canal is altogether very different from that of the fame animal in the perfect ftate. Long, narrow, and nearly of uniform diameter in the fmall inteftine, making irregular turns in its courfe, its volume augments at the rectum, which becomes of a facculated form, and makes two fpiral turns upon itfelf, before it proceeds to the anus. There is no valve feparating the two portions of the inteftine.

In the firen lacertina the inteftinal canal proceeds almoft in a ftraight courfe from the pylorus to the anus, making but one fmall turn near its middle, from which it proceeds ftraight to its termination. Its coats are tranfparent, and its diameter nearly equal throughout, not admitting of any divifion into fmall and large inteftines.

Phyfiology of the digeftive Organs.—Blumenbach afferts that moft reptiles are omnivorous, while fome are confined to one fpecies of food, as the bufo or rana calamita, which feeds on a few fpecies only of infects, and thofe alive. (Specimen Phyfiol. Comp. p. 29.) We cannot help doubting the accuracy of the firft part of this ftatement: the food feems to us almoft entirely animal. Serpents, frogs, and lizards, live on the fmaller animals or infects; and even the turtles, which eat particular kinds of marine plants, feed alfo on the mollufca. The fimple ftomachs, the fimple and fhort alimentary canals of the whole order, correfpond very clearly to what we underftand concerning their carnivorous habits. Newts feem to care for living infects and worms only, which they feize with their jaws, and fwallow whole.

Two apparently contradictory circumftances have been noticed in this order; great voracity in many inftances, but in all a wonderful power of abftinence. Salamanders fometimes devour their own excrement, and earth. Serpents often take in a quantity of food, which diftends their bodies inordinately, and leaves them inactive, and hardly capable of motion. The falamanders will fometimes ftuff themfelves to fuch a degree with worms, that they crawl up again out of their ftomachs. See Spallanzani's Differtations, vol. i. p. 110.

"A newt," fays Bonnet, "having devoured a large earthworm, I fupplied it with another above four inches long, and thick in proportion. It immediately fwallowed the whole, except a line or two that hung out of the mouth; but the worm was foon thrown up, and the fame repeated twice, but the worm ftill lived." Spallanzani's Tracts, vol. ii. p. 366.

The inftances which are recorded of the abftinence of reptiles feem at firft almoft incredible. Not to mention the toads,

toads which have been found inclofed in blocks of ftone, and which probably have been in a torpid ftate, nor the more common inftances (fee L. Th. Gronovius ad Plinium de Aquatilium Natura, p. 38.) we have the refpectable authority of Caldefi for the fact of tortoifes having remained without food, and not in a torpid ftate, for a year and a half. Blumenbach reports of a tortoife, which he kept for three quarters of a year, that the harmlefs creature never ate any thing the whole time, although every thing that the houfe and garden afforded was offered to him. For the laft three months (from November to February) he exhibited the loweft degree of vitality, manifefted, in addition to extremely flow locomotion, with almoft clofed eye-lids, merely by the fingle fenfe of touch or feeling, particularly of warmth and drafts of air. When he died, the mufcles were as flefhy and frefh-coloured as in the beft nourifhed tortoifes. Abbildungen, &c. No. 66.

Redi had a land tortoife live eighteen months, a cameleon eight, and vipers ten, without food. (Spallanzani's Tracts, Introduction, p. 42.) Toads were quite lively at the end of fourteen and eighteen months, inclofed in pots. Ibid.

Blafius mentions, in his "Anatomia Animalium," that a land tortoife which he kept ten months would take no food during the whole time.

Bonnet, fpeaking of newts, fays, "thefe animals can fupport the want of food very long. Some of mine have lived two months without it. Sign. Spallanzani had remarked the fame; and obferved, that although long deprived of nutriment, they reproduced their members equally well as thofe plentifully fupplied with fuftenance." (Spallanzani's Tracts, v. 2. p. 364.) Blumenbach has kept falamanders eight months without taking food, or appearing to fuffer from the want of it. (Handbuch der Natur gefchichte, p. 220.) Daudin afferts that fnakes and vipers may be kept for fix months without food, yet feem to lofe none of their activity: t. 1. Introd. p. 270.

Some protei, which Dr. Schreibers of Vienna had kept in his poffeffion for two years, had taken no food, and were quite well. (Cuvier, Rech. fur quelques Rept. douteux; l'Anat. du Proté.) Bruce ftated that he had kept the ceraftes in a bottle for two years without food, and Lacépéde reports, on the authority of Shaw, that a Venetian apothecary kept two of thefe fafting for five years. (See Daudin, vol. vi. p. 186.) This power of fafting belongs, in a greater or lefs degree, to the whole order. For a comparifon between the power of abftinence of warm-blooded animals and reptiles (the ftate of torpidity being excepted), fee Diff. Academ. Inftit. Bonon. ap Benedictum 14. Pont. Max. de fervor. Dei Beatificatione, lib. 4. p. 1. pag. 328.; alfo Beccarius in Comm. Inftit. Bonon. t. 2. p. 1. pag. 223.

No reptiles mafticate: the herbivorous amphibia gnaw off the vegetable productions on which they feed, but they do not chew them. The ftructure of their jaws, teeth, and tongue, gives them the power of fwallowing entire animals: this procefs of deglutition, being often exercifed on animals as broad as themfelves, and broader, is very flow, and occupies even hours. The œfophagus muft of courfe poffefs a great power of dilatation. In his account of the newt, Bonnet fays, "that worms are feized with a fudden motion of the animal's jaws, and fwallowed alive, with gentle fhocks of the whole body, and particularly of the anterior part. The prey is always fwallowed without maftication: the minute teeth, which are not employed in chewing, ferve to prevent the efcape of the animal, which twifts itfelf about moft actively. Long worms are devoured entire, notwithftanding all their exertions to efcape. They twine round the neck of the newt like a ferpent: every moment they become fhorter, and gradually difappear. Thus have I feen a newt fwallow a worm more than fix inches long in lefs than five minutes. A large worm, feized by the middle, is feldom fwallowed in the fame pofition, becaufe it is too large, if doubled in the mouth, and the newt gradually fhakes it out, until it can feize one of the extremities; which being accomplifhed, the worm is foon devoured. However, I have obferved a large one fwallow a worm taken by the middle, without feizing an extremity; but a quarter of an hour was occupied in the meal. The fucceffive motions of deglutition are very fenfible; it is performed by repeated fhocks. Though they have flexible jointed fingers, they make no ufe of the hand, either to feize their prey, convey it to the mouth, or retain it there." Spallanzani's Tracts, v. 2. p. 364.

The length and capacity of this tube, and its large communication with the ftomach, are well fuited to the nature of ferpents. The prey, always fwallowed without maftication, is often too long to pafs entirely into the ftomach: it remains in the œfophagus until room is made for it. Travellers have even afferted that one end of an animal fometimes hangs out of a ferpent's mouth, while the other is in the ftomach.

As there is no maftication in this clafs, nor any provifion like the gizzard of birds, for comminuting the food when fwallowed, the procefs of digeftion muft be effected by the action of the ftomach alone on the prey fwallowed entire. The juices of the organ are fully adequate to this effect; and the procefs has been demonftrated by experiment in feveral genera by Spallanzani. He inclofed food in tubes, and conveyed them into the ftomach of the frog, the newt, and different ferpents; and always found that it was diffolved in a longer or fhorter time: it thus appears that the effential nature of digeftion is the fame as in the warm-blooded animals: but the procefs exhibits fome modifications, as the different nature and habits of the animals would naturally lead us to expect. The chief difference is that the folution requires a confiderably longer time than in warm-blooded animals. The flefh in the tubes, conveyed into the ftomachs of frogs, was not completely diffolved until the third and even the fifth day. (Differtations, v. 1. p. 102.) Yet although the gaftric liquor of frogs acts fo flowly, it is capable in time of diffolving even bone: Spallanzani met with a moufe in the ftomach of a frog; all the foft parts of the limbs were gone, fo as to have only the naked bones, which were confiderably wafted, and converted into a femi-gelatinous fubftance. (Ibid. p. 102.) Earth-worms enclofed in tubes were converted into a whitifh pulp in thirty hours, in the ftomach of the water newt; p. 104. He found numerous fmall white worms in the ftomachs of three-fourths of all the newts he examined, from five or fix in number to a hundred and more. Thefe were fo delicate that they would not bear even flight preffure; and thus afford a proof that nothing like trituration can go on in the ftomach, but that digeftion is fimply folution by the gaftric liquor; p. 104—111. In ferpents the procefs occupied from two to five days. The tibiæ of frogs were almoft completely diffolved in five days; § 118—122. As the animals fwallowed by ferpents often lie in part in the œfophagus, a queftion arifes, whether they undergo any digeftion in that tube, or whether this function be the exclufive attribute of the ftomach. A viper, fays Charas (Defcrip. Anat. de la Vipère,) vomited a lizard, which had been fwallowed twelve days before. All the front of the body, which had been in the ftomach, had merely

merely the bones remaining, while the other parts were nearly as perfect as if they had been fwallowed the fame day. Spallanzani confirmed this want of digeftive power in the œfophagus, by direct experiment ; § 125. Naturalifts, fays this indefatigable inquirer, were already apprized of the tardinefs of digeftion in ferpents. Bomare, in his Dict. d'Hift. Naturelle, gives an account of a ferpent at Martinique, which retained a chicken in its ftomach for three months, and did not completely digeft it. "It is remarkable that flefh does not become fœtid from remaining long in the ftomachs of thefe cold animals, which I had occafion to obferve particularly in a viper. A lizard was retained in its ftomach for fixteen days, at the end of which time it had no odour but that of the gaftric juice. Yet fuch was the heat of the feafon, that another lizard, which I had placed in a clofe veffel, containing a little water, emitted an infupportable ftench before the expiration of the third day ; § 127. The gaftric liquor of a fnake approaches in colour to that of foot ; it had the fluidity of water, and evaporated very flowly ; it had both a falt and bitter tafte, and was not inflammable. It ftrongly refembled the gaftric fluid of other animals, and this refemblance extended to the odour, which was exactly like that of the correfponding juices of birds of prey ; § 123.

The idea of Blumenbach, that the venom of the poifonous ferpents fupplies the place of maftication, and promotes digeftion by fome feptic power, feems completely unfounded. It is a provifion calculated merely for purpofes of offence. Where is this feptic power, or what fupplies its place in the harmlefs ferpents, and in all other amphibia ?

The whole alimentary canal of the amphibia abounds with a vifcid tenacious mucus, the abode of feveral genera of worms.

Blumenbach failed completely in very numerous and diverfified attempts to cram frogs and lizards with madder root, and thus to produce in their bones that beautiful rofe colour, which is fo quickly produced in the mammalia of birds, when thus fed. Specimen Phyfiol. p. 31.

Abforbing Veffels. —This fyftem has been very little examined by anatomifts, probably on account of the minutenefs of the tubes, and the confequent difficulty of injecting them. We have nothing to add to the account given by Hewfon, who firft defcribed them in the Philofophical Tranfactions, 1769.

No lymphatic gland has been yet feen in a reptile : birds have none in their mefentery, but they are feen connected to the large lymphatics of the neck.

It has been afferted that the chyle is colourlefs, and hence anatomifts have explained why the veffels were fo long undifcovered. In animals which have white chyle, the appearance of this fluid through the tranfparent coats of the lacteals fupplies the place of injection, and affords an eafy method of demonftrating them. Mr. Hewfon ftates that he faw white chyle in a crocodile.

The diftribution of the lacteals (if that term may be employed where the chyle, inftead of being like milk, is tranfparent) on the inteftine of the turtle, forms one of the moft elegant preparations in comparative anatomy. By fixing the injecting tube in a veffel near the inteftine, and waiting with a little patience, the quickfilver will gradually find its way into the minute ramifications of the lacteals. The large trunks on the mefentery contain valves, fo that we cannot fucceed in filling the abforbents of the inteftine from them ; but the ramifications on the inteftine itfelf are deftitute of thefe folds, fo that when once the quickfilver has reached the furface of the gut, it will run forward without any obftacle. The peritoneal furface of the gut is completely covered with ftraight parallel branches, running according to the length of the inteftine. Its inner furface is no lefs thickly covered with lacteals of a different appearance. When dried it feems as if the quickfilver were contained in fmall cells, covering the whole internal furface of the inteftine fo completely, that the point of a pin could fcarcely be placed between them. Mr. Hewfon has particularly defcribed this appearance, and was doubtful whether it ought to be referred to extravafation or not. But we are convinced, from frequent examinations of this cellular ftructure, that it is a part of the natural organization ; becaufe the cells are regular and uniform in their fize and arrangement ; no force is ufed in the experiment ; and a real extravafation prefents an appearance altogether different. The extent of the abforbing fyftem, as demonftrated in this way, is beyond any thing we could form an idea of from injections in man or warm-blooded animals.

After leaving the inteftine, the lacteals accompany the blood-veffels on the mefentery, running at their fides, and communicating acrofs them. Each artery has two veins, and there is a lacteal or more at each fide of each of the three veffels ; fo that their number confiderably exceeds that of the blood-veffels. A coarfe reprefentation of them, on the mefentery, is exhibited in Monro's Phyfiology of Fifhes, tab. 30.

Near the root of the mefentery the large lacteals anaftomofe, fo as to form a net-work, from which feveral large branches go into fome confiderable lymphatics on the left fide of the fpine. Thefe laft can be traced downwards almoft to the anus, and belong to the parts fituated below the mefentery, and particularly to the kidnies. At the root of the mefentery, on the left fide of the fpine, the lymphatics of the fpleen join the lacteals, and immediately above this union a fort of plexus or net-work is formed, which lies upon the right aorta. Flom this plexus a large branch arifes, which paffes behind the right aorta to the left fide, and gets before the left aorta, where it affifts in forming a large receptaculum, lying in front of that artery. The thoracic ducts arife from this receptaculum. From its right fide goes one trunk, which is joined by that large branch which came from the plexus to the left fide of the right aorta, and then paffes over the fpine. This trunk is the thoracic duct of the right fide ; for having got to the right fide of the fpine, it runs upwards on the infide of the right aorta, towards the right fubclavian vein. And when it has advanced a little above the lungs, or within three or four inches of the fubclavian vein, it divides into branches, which, near the fame place, are joined by a large branch that comes up on the outfide of the aorta. From this part upwards, thofe veffels divide and fubdivide, and are afterwards joined by the lymphatics of the neck, which likewife divide into branches before they join thofe from below ; fo that between the thoracic duct and the lymphatics of the fame fide of the neck a very intricate net-work is formed. From this net-work a branch goes into the angle made by the jugular vein, and the lower part, or trunk, of the fubclavian : this branch, therefore, lies on the infide of the jugular, whilft another gets to the outfide of that vein, and feems to open into it a little above the angle between that vein and the fubclavian. Into the above-mentioned receptaculum the lymphatics of the ftomach and duodenum enter : they have numerous anaftomofes, forming a beautiful net-work round the artery which they accompany. From this receptaculum likewife, befides the trunk already mentioned, which goes to the right fide, arife two other trunks, nearly equal in fize ; one of which runs upon the left fide, and the other upon the right fide of the left aorta, till they come within two or three inches of the left

left ſubclavian vein; where they join behind the aorta, and form a number of branches, which are afterwards joined by the lymphatics of the left ſide of the neck: ſo that here a net-work or plexus is formed, as upon the right ſide. From this plexus a branch iſſues, which opens into the angle between the jugular and the lower part or trunk of the ſubclavian vein. In theſe net-works, formed by the lymphatics near their termination in the veins, this ſyſtem in the turtle differs remarkably from that in birds. Hewſon's Account of the Lymphatic Syſtem in Amphibious Animals, Philoſ. Tranſ. vol. 69. p. 198.

The Liver, which is divided in the mammalia into ſeveral lobes diſtinct from each other, and is more uniform in birds, is ſtill leſs divided in reptiles. Often it has no diviſion of lobes, but is merely irregularly fiſſured on its looſe and thin edge. Its proportionate ſize, however, is more conſiderable than in the two claſſes juſt mentioned. Occupying uſually the two hypochondria, it extends far backwards under the inteſtines, and is ſupported in its poſition by folds of the peritoneum, analogous to thoſe which exiſt in the mammalia. Its colour is no longer that reddiſh-brown which is ſeen in the mammalia and birds; but it partakes more of yellow.

In the chelonians the liver exhibits a peculiar arrangement, being divided into two rounded irregular maſſes, of which the right occupies the ſame hypochondrium, and the other is connected to the ſmall curvature of the ſtomach. They are united by two narrow productions of the ſame ſubſtance, in which the principal veſſels paſs. In the green lizard, the geckos, the dragons, the iguanas, it forms a ſingle maſs of various figure, flat or convex below, concave above. Its looſe edge has two fiſſures in the dragon, dividing it into three lobes, of which the right is prolonged into a ſort of tail. There is only one fiſſure in the geckos, and the right part is equally more extenſive than the left. In the common iguana it is lengthened into a long appendix. In the crocodile and cameleon the liver has two very diſtinct lobes; and moreover, in the latter, a long appendix. It has only one lobe in the ſerpents, in whom it is long and cylindrical. Like other organs, it aſſumes in this order a figure correſponding to the elongated form of their bodies. There is one lobe only in the ſalamanders, but two in the other batracians.

Hepatic Canals.—The common trunk of theſe canals is uſually ſeparate from the cyſtic duct, and not inſerted with the latter in the inteſtinal canal, in reptiles, as well as in birds. This has been obſerved in the chelonian and ſaurian orders, in ſeveral ophidians, and ſome batracians. Yet this arrangement is not conſtant. For, in the crocodile, where the hepatic is ſometimes ſeparate from the cyſtic duct, it ſends at other times a branch to the gall-bladder, which is inſerted a little above its neck, and is itſelf united to the cyſtic canal, not far from the inteſtine. The mouth of the common canal was diſtant from the pylorus, ſays Cuvier, 0.26 in a crocodile, whoſe whole inteſtinal canal was rather more than a metre (about 39½ inches) in length.

In the teſtudo græca the hepatic canal ſends a branch of communication to the cyſtic canal, not far from the gall-bladder; but theſe two canals open ſeparately into the inteſtine, though near each other; the former before the latter.

The Gall-Bladder has its fundus uſually directed backwards. Its proportional volume is leſs conſiderable than in mammalia and birds; and it is more intimately connected with the liver than in theſe claſſes. In the teſtudines it is almoſt entirely concealed in the right lobe of the viſcus; and is placed under the ſame lobe in the crocodile. Where the liver is not divided into lobes, the ſituation of this reſervoir is marked out by a fiſſure. In the ophidians the gall-bladder is abſolutely ſeparated from the liver, and ſituated at the ſide of the ſtomach, near the pylorus, a ſhort diſtance beyond the poſterior extremity of that viſcus. Its form is generally oval, but it approaches to the cylindrical figure in the iguana.

The connections of the cyſtic and hepatic canals have been already mentioned. The former remains generally diſtinct from the latter, by the ſide of which it is inſerted into the inteſtine. Sometimes it receives the branches of the latter in ſucceſſion.

The Pancreas is a conglomerate gland, as in mammalia and birds, and poſſeſſes the ſame ſtructure (with ſome unimportant modifications of colour, conſiſtence, lobular diviſions, &c.) as in man. Its poſition and figure vary in reptiles. In ſeveral chelonians it is triangular. That of the Nilotic crocodile is divided into lobes: it is irregular in the ophidians, and ſituated on the right of the origin of the inteſtinal canal. In the frog its figure is equally irregular, and it is ſituated in the arc formed by the ſtomach towards the front. It is placed in the firſt curve of the inteſtine in the ſalamander.

There is either a ſingle or double pancreatic canal. In the Nilotic crocodile, for example, there are two, inſerted in the inteſtine after the biliary canals, while there is only one in the land ſalamander, the inſertion of which precedes that of the biliary tubes.

The Spleen.—This is a viſcus, of which the uſe is not hitherto underſtood. It exiſts in all the vertebral animals; but its importance ſeems to diminiſh as we paſs from mammalia to birds, from the latter to reptiles, and from theſe again to fiſhes; at leaſt, if we may judge from the ſucceſſive diminution of its volume in theſe four claſſes.

Its figure varies conſiderably in this claſs. It is ſhaped like the kidney in the teſtudines; ſmall and ſpherical in the frogs and toads; elongated in the ſalamanders, as well as in the ſaurian and ophidian orders.

The abdominal Cavity, Peritoneum, and its Proceſſes.—The offices of this membrane, in covering and inſulating the various viſcera, confining them, by its continuations and folds, more or leſs cloſely to the ſides of the cavity, and facilitating, by its ſmooth ſurface, their motions with reſpect to each other, and to the containing cavity, will convince us of the importance of the membrane, and lead us to expect that it ſhould exiſt very generally. We, conſequently, find it in all the vertebral animals. Generally white, delicate, and tranſparent, it is ſometimes black in reptiles.

In this claſs, as in birds, there is no diaphragm, and conſequently no diſtinction of abdominal and thoracic cavities. All the viſcera are contained in one large cavity, and ſurrounded by one membrane. Geoffroy, however, deſcribes ſome muſcular fibres coming from the ſternum, and fixed to a membrane covering the convexity of the liver, which ſeem like the rudiment of a diaphragm. Annales du Muſeum, v. ii. p. 50.

In the chelonians, the membrane produces certain ſubdiviſions of the common cavity of the thorax and abdomen. We remark, 1ſt, the cavity of the lungs, which are continued far backwards, above the heart, liver, and inteſtines; 2dly, that of the heart, or pericardium, which touches the following behind; 3dly, that of the abdominal viſcera, containing the ſtomach, liver, inteſtines, ovaries, teſticles, and urinary bladder. In front it covers the liver, forming a ſort of membranous diaphragm, ſeparating it from the heart; and it cloſes the cavity of the pelvis behind. It alſo furniſhes the meſenteric folds. The texture of this membrane appears ſtronger in the teſtudines than in other reptiles.

 The

The mefentery exhibits, in the different orders of reptiles, fome varieties, which we fhall fhortly notice. The firft fold, which is attached to the fmall inteftine in the teftudines, does not come immediately from the vertebral column, and does not form the mefentery properly fo called, until after it has fixed the arch of the colon by means of a mefocolon. The duodenum is confined in the right hypochondrium, and loins, by laminæ of the common membrane, which cover it, and are then continued to the abdominal parietes. The mefentery of ferpents is a narrow fold, not coming immediately from the vertebral column: the blood-veffels form numerous anaftomofes between its laminæ, as in warm-blooded animals.

The faurians have a mefentery tolerably developed. The production, which goes to the large inteftine, like that which belongs to the fmall, comes from the vertebral column. There is no tranfverfe mefocolon.

Reptiles have no *omenta;* but ftructures apparently analogous to thefe fatty membranes occur in fome of them. The ferpents have membranous proceffes, containing much fat, and extending, like the great omentum of the mammalia, under the inteftinal canal. Many faurians have alfo two productions of peritoneum, loaded with fat, advancing from the front edge of the pelvis under the abdominal vifcera; there are fatty lobes attached to the tefticles and ovaries of frogs. The latter are not regarded by Blumenbach in the light of omenta. " The yellow appendices," fays he, (ductus adipofi, appendices luteæ,) " which are found in the frog, on either fide of the fpine, and fometimes form one mafs, fometimes are divided into feveral fmaller portions, were confidered by Malpighi as a kind of omentum. (De omento et adipofis ductibus, oper. t. 2. p. 35, &c.) That this refemblance is very remote, appears from feveral circumftances; and particularly from the conftant and remarkable variations of fize which occur in thefe parts at the pairing feafon." Comparative Anatomy, tranflated by Lawrence, p. 193.

Thefe bodies, being apparently connected to the tefticles and ovaries, are defcribed with the generative organs by Swammerdam and Roefel. They confift of a pedicle, attached more particularly to the emulgent vein on each fide, and of two, three, to feven or more pieces joined to it, varying in fize according to the age and feafon. They are proportionally large in the tadpole. They may be feen fmall in female frogs, which have not yet laid their ova, although Roefel afferts that they increafe in fize with the generative organs. In this fmall ftate, Cuvier obferves, that a veffel, filled with venous blood, and producing no branches, may be feen in the axis of each fringed portion. Thefe veffels all join to form a common trunk in the pedicle; and this trunk terminates in the emulgent vein.

The abfence of omentum in this clafs does not accord with its fuppofed ufe to keep the inteftines warm. Is there any proof that the inteftines are warmer with it, than they would be without it? And is there not as great a neceffity for preventing the efcape of heat in reptiles, or in birds, (which alfo have no omentum,) as in the mammalia? Cuvier obferves, that many of the hybernating mammalia have two lateral omental appendices, which, with the principal omentum, are abundantly furnifhed with fat in the winter, fo as to form " an adipous covering for the inteftines, which no doubt contributes powerfully to retain their natural heat, to prevent the accefs of cold, and to fupply the place of food." All reptiles are torpid in the winter, yet they have no omenta.

Urinary Organs.

The Kidnies.—Thefe are diftinguifhed from the fame glands in mammalia, and refemble thofe of birds and fifhes, in the impoffibility of diftinguifhing in them the two fubftances (fee KIDNEY), and in the abfence of infundibula and pelvis. Their fituation, form, and relative fize, vary in the different orders.

In the chelonians and faurians, they lie far back in the abdominal cavity. They adhere clofely to the pelvis in the lizards properly fo called, under the facrum, and penetrate even under the tail; they go as far back, but they advance farther in front, in the falamanders. They lie altogether farther forwards, and very near each other, in the other batracians. In thefe three orders both kidnies are fituated at the fame height, and covered by the peritoneum on their inferior furface only. In the ophidians, the right is placed further forwards than the left; and they are connected, on each fide of the vertebral column, merely by a prolongation of peritoneum, which furrounds and fufpends them, without fixing them to the fpine. There is a manifeft relation between the peculiar arrangement, and the great mobility of the column in thefe animals.

Their form is fhort and thick in the chelonians, more or lefs elongated and flattened oval in the faurians and batracians, and extremely elongated in the ophidians. They confift, in the latter, of numerous feparate lobes, placed in a chain one before the other. They are alfo minutely divided in the chelonians, at leaft on their two furfaces; for all the lobes are united in the centre. They form, on their furface, a kind of convolutions refembling thofe of the brain, and giving the glands a peculiar afpect.

Among the faurians, the crocodiles have them much divided, at leaft at a certain age. In a fmall crocodile, about a foot in length, Cuvier faw no divifion, while there were many in a larger individual of the fame fpecies. It would be fingular if this fhould turn out to be a conftant difference, as it is exactly the converfe of that which exifts in man. They are without lobes, or only flightly divided in other genera of the fame order. They have no divifions in the batracians.

The origin of the ureters is analogous to that of birds; and their length varies according to the fituation of the kidnies.

They end in the urethra in the chelonians, and the urine paffes from that canal into the bladder.

They are fhort, large, and thick-fided in the crocodile, and pierce the fuperior furface of the cloaca, at a confiderable diftance from each other.

The principal ramifications of the urinary canals are eafily feen in the ophidians, ending fucceffively, as they come out of each lobe, in a common trunk, which follows the internal edge of the kidney, and forms the ureter. Arriving near the cloaca, each is dilated into a fmall oval bag, and then terminates feparately.

In general they terminate in the cloaca or bladder, according as the latter refervoir exifts or not.

Urinary Bladder.—Reptiles vary much in refpect to the exiftence of this part. The chelonian and batracian orders have it: and it is found in the following genera of faurians; *viz.* the iguana, tupinambis, cameleon, dragon, ftellio: while it is wanting in the crocodile, lizard, agame, gecko, other genera of the fame order; and in the ophidians.

The bladder is very large, with thin fides and weak mufcular fibres in the chelonians; and it has a more or lefs marked divifion at its fundus into two portions. A very fhort urethra opens on the inferior furface of the cloaca: its cavity prefents two prominences on each fide, of which the anterior is pierced by the orifice of the vas deferens, the pofterior by that of the ureter.

The

The bladder always receives the urine by its neck, or by a beginning of an urethra, which opens immediately into the cloaca.

There are two large membranous bags in the frog and toad, occupying the situation of the urinary bladder, generally considered as such, and so described by Blumenbach and Cuvier. Townson doubts whether they ought to be considered as part of the urinary apparatus. (See his Tracts and Observations, p. 66. tab. 3.) They have no connection with the ureters. Indeed it is very clear, that the latter tubes open on the superior surface; while these two receptacles terminate on the inferior surface of that intestine. They contain a pure water. Their size, which exceeds all ordinary proportion to the bulk of the kidney, renders it likewise probable that they are not receptacles of urine.

Renal Capsules.—The parts to which this name has been given, and which are found in the three first orders of reptiles, are still smaller in proportion, than in mammalia and birds, and are completely separate from the kidnies. In the chelonians they are connected to the emulgent veins. In the saurians and ophidians they lie in the fold of the peritoneum, which unites the ovaries and oviducts.

For a description of the fringed fatty appendices, which are found in the batracian order near the testicles and ovaries, and the vessels of which join the emulgent veins, see the account of the omenta.

Organs of Circulation.—The whole of nutrition is effected at one operation in zoophytes: chyle passes into the parts in proportion as it is made; in insects also it bathes them as soon as it is formed, and they appropriate it. In the superior animals, there is an intermediate operation: a particular fluid only, always moving in a certain system of vessels, immediately nourishes the parts; and this fluid is renewed by the chyle. The motion of this peculiar fluid, of this blood, is called circulation;—a process confined to the superior classes, that is, to the vertebral animals, the mollusca, the worms, and the crustacea.

There are two principal points for our consideration in the circulation; its agents, and the routes of the blood.

That part of the latter is particularly interesting, which conducts the blood to the respiratory organ. One of the chief purposes of the circulation is to conduct the blood constantly, in greater or smaller quantity, into an organ, where it may undergo the mediate or immediate action of oxygen; and, as the qualities of the blood depend much on the degree of force of this action, and in the modification which the blood receives from it, while all parts of the body, being nourished by this blood, partake of its qualities, it follows that the whole nature of an animal will be in some sort determined by the distribution of its circulating organs, and by the route which this distribution marks out for the blood.

Hence arises the importance of the structure of the heart, in reference to natural history, and the correctness of the characters drawn from it for the formation of classes. Men of genius had foreseen, rather than demonstrated this importance; but it has been established on rational principles only in modern times.

The circulations through the body and the lung are called, respectively, the great and the minor. In the former, all the blood returning from the body by the *veins*, which joining together from all parts, ultimately end in one trunk, goes again to these parts by the *arteries*, of which a common trunk is gradually divided and sub-divided, until the last divisions, as well as their union with the roots of the veins, escape the eye.

If the common trunk of the veins communicated directly with the common arterial trunk, there would be a single circulation; the blood brought back to the centre, would be sent again immediately to the parts, to return again directly, and so on; but this never takes place entirely.

Before the blood, brought back to the common trunk of the veins, can again enter that of the arteries, it must be sent in part, or altogether, to the pulmonary organ, in order to undergo the action of the atmosphere.

If the circulating organs be so arranged that every drop of the blood goes through the lung, by the minor circulation, before it can enter the arterial trunk, the common trunk of the veins of the body sending all its blood into the pulmonary arterial trunk, whose ultimate ramifications communicate with veins united into a common trunk, sending all its blood into that of the arteries of the body, there is a *double circulation*.

If, on the contrary, the common trunk of the general veins, instead of being distributed entirely to the lung, should only send to it a branch, while the rest of its blood should go directly into the common trunk of the general arteries, the minor circulation would be only a fraction of the great, more or less considerable, according to the size of the branch devoted to it. In each circuit of the blood, respiration would be exercised on a part only of this fluid, and the rest would go again into the body by the arteries, without having passed through the lung. This blood, and the parts nourished by it, would participate less, ceteris paribus, in the qualities which respiration could impart to it. This is what takes place in reptiles; their pulmonary circulation is only a fraction of the great, more or less considerable in the different genera. The other classes, *viz.* the mammalia, birds, fishes, mollusca, and worms, have a double circulation, and no part of their blood can return into the great, until it has gone through the minor circulation.

Yet we are not to conclude that the ultimate effect of respiration is the same, because circulation is the same. The mode of respiration may be different, and, as this is one of the factors, the product will be affected by its alteration. All the animals last enumerated have an entire pulmonary circulation, while, in reptiles, it is only a fraction: let them be, for example, as 1 to $\frac{1}{2}$. Now fishes, mollusca, and worms, breathing in water, and that oxygen only, which is mixed and contained in this water, may be considered as having a half-respiration, while reptiles, breathing air itself, have an entire one. An entire respiration, multiplied by a half-circulation, and a half-circulation by an entire respiration, give the same product; which is, in both cases, a half-oxygenation of the blood, using this term merely to express the changes taking place from breathing.

Mammalia have an entire circulation and respiration; and consequently an entire oxygenation. The quantity of the latter is even greater in birds in consequence of the peculiar manner in which air is introduced into all parts of their body.

The fraction of $\frac{1}{2}$ is only adopted for the purpose of illustration; the quantity probably varies in the different genera of each class, and cannot be rigorously appreciated.

By these considerations we may estimate, and in a manner calculate, the nature of each animal. As respiration gives to the blood its heat and energy, and through its medium imparts excitability to the organs, its quantity will determine the degree of vigour in the animal functions. Hence we deduce the great force of the moving powers, the acuteness of the senses, the rapidity of digestion, and the heat of the passions in birds. Hence the more moderate degree of all these in the mammalia; hence the inertness, the inactivity, and apparent stupidity, of the other classes. Hence, too, the various modifications of vital temperature natural to each

each of thefe claffes, which are in an exact ratio to the degree of their other qualities.

The circulation is effected by means of mufcular powers, which are applied particularly to the arterial fyftem; the venous feeming to be merely paffive. A hollow mufcle, called a *ventricle*, poffeffing great and continued irritability, and contracting forcibly on the blood whenever it arrives, is placed at the union of the venous and the correfponding arterial trunk. Valves are placed at its two openings; one valve allows the blood to enter, and prevents it from going back again, while the other permits its exit, and cuts off the return. The ventricle then cannot contract without diftending the arteries, pufhing forwards the blood, which they contain already, and thus producing the *pulfe*. The ventricle, having expelled the blood which irritated it, is relaxed and dilated, and then immediately filled with a frefh quantity of blood from the veins. Before entering the ventricle, the vein is dilated into a mufcular fac, called the *auricle*, with much lefs confiderable mufcular fides. This is irritated by the blood received from the vein, contracts on it, and fends it into the ventricle. It is hardly neceffary to add, that the auricle and ventricle contract alternately.

Animals with a fimple circulation have a fingle ventricle; but they poffefs fometimes two auricles. When the circulation is double, there may be a ventricle at the origin of each artery, or at that of one only. Mammalia and birds have two, and the fepiæ among the mollufca.

All other animals have a ventricle at the origin of one only of the two arteries, but not of the fame in all. It is placed, in fifhes, at the origin of the pulmonary artery; in the mollufca at the origin of the artery of the body, or the *aorta*, which is the name of that artery.

The union of the auricle and ventricle conftitutes the *heart*. We find, therefore, in fifhes and mollufca, a fimple heart, *pulmonary* in the former, *aortic* in the latter. Reptiles, alfo, have a fimple heart, at once pulmonary and aortic. Mammalia, birds, and fepiæ, have a double heart, or rather two, a pulmonary and an aortic, hearts.

In mammalia and birds the two hearts are united, and form one mafs, which commonly bears the name of heart, as if it were a fingle organ. This is not the cafe in the fepiæ. See VERMES, in *Comparative Anatomy*.

We may now underftand what naturalifts mean, when they fay that mammalia and birds have a heart with two auricles and two ventricles; reptiles and fifhes a heart with a fingle auricle and ventricle. The latter phrafe, befides comprifing, in a common expreffion, two things really very different, contains alfo an error of fact; for many reptiles have two auricles.

Refpecting the hearts of mammalia, birds, fifhes, and mollufca, fee the articles MAMMALIA, BIRDS, FISHES, and VERMES, in *Comparative Anatomy*. For the phyfiology of the circulation, the powers and actions of the heart, and the other organs concerned in it, fee CIRCULATION and HEART.

The effential ftructure of the heart is the fame in all animals; there are only modifications of greater or lefs importance. It is covered externally by a fmooth membrane, the reflected portion of the pericardium; its cavities are lined by another fmooth membrane, continuous with the linings of the blood-veffels; and there is more or lefs mufcular fubftance interpofed between them. The exiftence of the pericardium is as general as that of the heart; its nature and difpofition are fo nearly alike in all animals, that it is not worth while to notice the modifications.

Of the Heart.—In the different orders of reptiles, the heart is found to vary in fome parts of its ftructure; there is, however, no effential difference, when viewed in relation to its functions. The three firft orders have a heart confifting of two auricles and a fingle ventricle, which is fometimes divided into many cavities, communicating with each other. On the other hand, in the batracians there is but a fingle auricle and ventricle, with its cavity of a fimple form. We fhall enumerate fucceffively the differences of ftructure in the four orders of this clafs of animals.

Firft in the chelonians. In the animals compofing this order, the heart has a form altogether peculiar. The length of the organ is much exceeded by its breadth; in fome inftances, it refembles the fegment of a fphere; in others, it is of a fquare but elongated form, and curved in its longitudinal direction. In its natural fituation, it is found beneath the lungs, in front of the liver, and partly between the two lobes of the latter. The pericardium, which is capacious and ftrong, is in contact with the membrane invefting thofe organs, and is as firmly adherent to it as the pericardium is to the diaphragm in man.

The magnitude of the two auricles is much greater in proportion, than in any animals of the claffes of mammalia or birds; the capacity of each is at leaft equal to that of the ventricle; they are fituated in part above the latter, projecting upon its lateral and anterior parts. They poffefs fomewhat of a rounded form, are without any appendix, and have their parietes thin, with fome flefhy fafciculi in their ftructure. The right auricle, which exceeds in a trifling degree the fize of the left, receives, by a fingle opening at its upper part, the blood returning from the body. Two valves are placed around the borders of the opening, giving it the appearance of a fimple fiffure. The pulmonary veins alone terminate in the oppofite auricle; their termination is provided in the fame manner with two valves. A fimple membranous partition feparates the cavities of the two auricles and their openings into the ventricle. It is on the ventricle that depends the form which we have defcribed as belonging to the heart. Its cavity is very fmall in comparifon to its fize, which is owing to the great thicknefs of the parietes. Thefe are found to be compofed exteriorly of a moderately thick layer of fibres, which have a direction parallel to the external furface of the ventricle. Beneath thefe, there are other numerous mufcular fafciculi, varying in their direction, but proceeding principally from the fuperior to the inferior furface; the greater number of them are only contiguous, or feparated from each other, allowing the blood to pafs through the intervals formed between them as through a fponge. It refults from this ftructure, that the cavity of the ventricle is diminifhed to one-third of its volume; it occupies the middle and right fide of its bafe. In its greater part, it is lined by a continuation of the membranous fold which covers the auricular orifices, performing to them the office of a valve; it is of a fquare form, attached at the middle of its external furface to the partition between the auricles, and by its fuperior and inferior fides to the correfponding parietes of the ventricle; it is only loofe and unconnected in its right and left borders. The firft is extended over the opening of the auricle on the fame fide, and the latter over that of the oppofite auricle; fo that thefe openings appear in the ventricle feparated by the breadth of the fold, while in the auricles there is but the thin feptum intervening between them. The blood returning from the lungs into the left auricle is directed into the ventricle by means of the valve belonging to the former, in a courfe directly contrary to that leading to the opening belonging to the arteries of the body. It muft, therefore, neceffarily pafs through the whole cavity of the ventricle, from the left to the right, and

and into the intervals of the mufcular fafciculi compofing the parietes. From this ftructure it refults, that there muft be an admixture in the ventricle between the blood returning from the lungs, and that portion which has not been fubmitted to the influence of the furrounding element in its paffage through thofe organs. The opening between the right auricle and the cavity of the ventricle is in a fituation immediately directed towards the two cavities leading to the pulmonary arteries and arteries of the body; they are both fituated completely to the right, in the cavity of the ventricle. The firft, which is not always of the fame magnitude, is placed inferiorly to the other, having a wide communication with it. In fome inftances the opening is extended very far towards the pofterior part of the heart; in others it is fo fmall, as in the land tortoifes, that it does not exceed the diameter of the cavity leading to it. It is only in the firft conformation, of which we find examples in many of the fea tortoifes, that the appellation of pulmonary cavity can be applied to it. The blood arriving from the right auricle purfues a direction more particularly towards that part, by a channel leading from the one to the other. There is but one opening leading from the pulmonary cavity, which is that of the pulmonary artery; it is provided with two valves, and penetrates the bafe of the heart more inwardly than the openings to be next mentioned. Thefe are the terminations of the two aortæ, which are found near to each other on the right fide of the fuperior cavity, the fame which receives the blood of the two auricles. The termination of the left aorta is fituated a little more inwardly than that of the right, and inferiorly to it. They are each provided with two femicircular valves. This is the ftructure found in the fea tortoife; but in the land fpecies the arteries of the body arife by a fingle opening from the ventricle. The heart of the turtle is beft delineated by Mery, in the Acad. des Sciences, 1703.

In the fecond order of reptiles, the faurians, we fhall commence with a defcription of the heart of the crocodile, which prefents an example of the moft complicated ftructure that we have found in the animals of this order, or even in the whole clafs of reptiles. The pericardium is found, as in the chelonians, adhering to the peritoneum invefting the convex furface of the liver. The apex of the heart is connected by a very ftrong tendinous chord to the loofe part of that bag, which is extremely thick, and has a fibrous ftructure externally. In its natural fituation the organ is found occupying the fpace between the two lobes of the liver and the lungs on each fide. The fize of the auricles is fomewhat lefs than in the chelonians; in other refpects they are fimilar. The parietes are ftrengthened by flefhy fafciculi proceeding in different directions. The ventricle prefents an oval form, and has its parietes of great thicknefs. Its cavity is divided into three compartments, communicating by numerous openings. One of thefe divifions is fituated inferiorly and to the right. The auricle of the fame fide projects into its anterior part the blood received from the veins of the body by a wide opening, which is provided with two valves. The termination of the left defcending aorta is found in the fame cavity, in its left and anterior fide. Behind this latter opening is feen an orifice, which leads into the fmalleft of the three divifions, at the middle of the bafe of the heart, and in which is found the common trunk of the pulmonary arteries. It refults from this conformation, that there are two channels offered to the blood which has paffed from the right auricle into the cavity of the fame fide; the one by the left defcending aorta; the other into the cavity leading to the pulmonary artery. It may even take a third route, and pafs through the numerous holes which penetrate the partition feparating the fuperior and left cavities. The left auricle projects into the latter the blood received from the pulmonary veins. A membranous valve is found attached to the border of the opening on its right fide. The trunk common to the right defcending aorta, carotids, and axillary arteries, is fituate to the right of the valve. The blood muft either pafs into the arterial trunk, and from thence be diftributed to the head and extremities, or penetrate into the intervals between the flefhy fafciculi of that cavity, and from thence into the two others. It refults from this ftructure, that the blood diftributed to the anterior parts by the carotids and axillary arteries, to the pofterior parts by the iliacs, and to the tail by the middle facral artery, is nearly all derived immediately from the lungs, whilft a portion of that which is diftributed to the other vifcera by the left aorta comes from the right cavity and from the auricle of the fame fide, and confequently has not been modified by its paffage through thofe organs. The pulmonary blood is not fo intimately admixed with that from the body, as in the chelonians. Such is the ftructure of the heart in the crocodile of the Nile, and the caiman or American alligator. For a view of the crocodile's heart, fee Cuvier Leçons, t. 5. pl. 45.

It is lefs complicated in the common iguana (iguana delicatiffima). In this animal, the fituation of the heart is very remote from the liver, beneath the origin of the lungs, and in the moft projecting part of the cheft. It is of a conical form, being very broad at its bafe, and acute at its fummit. The auricles prefent nothing remarkable. In the ventricle, there are but two cavities, the one fituate to the right, which forms the proper cavity of the ventricle, the other to the left and fuperiorly, appearing as a finus of the former. The openings of the pulmonary auricle and right defcending aorta are found in the latter, nearly in the fame manner as in the crocodiles. The opening of the right auricle is fituated towards the middle of the great cavity or that of the ventricle, and is provided with a femilunar membranous valve, in the fame way as that of the left auricle. The orifices of the pulmonary artery and left defcending aorta are placed lower down in the fame cavity; the firft on the left, the other on the right. There is no pulmonary cavity. The interior of the ventricle is furnifhed with fafciculi of flefhy fibres.

The ftructure of the heart in the third order of reptiles, the ophidians, differs but in a trifling degree from that of the faurians, poffeffing the moft fimple conformation of this organ. There is no diftinct pulmonary cavity. The auricles are of confiderable fize; that which receives the blood from the body is the largeft. Their parietes are thin and tranfparent in the intervals between the flefhy fafciculi, by which their ftrength is augmented, and which are irregularly interlaced together. Their cavities are feparated by a membranous partition. The figure of the ventricle is generally that of an elongated cone, irregularly formed in confequence of an appendix of the fame figure, which projects from the left fide beyond its bafe. The interior is divided into two cavities, the one fuperior, the other inferior, the former being extended into the appendix. An imperfect feptum intervenes between them, having a loofe unconnected edge on its right fide, and is extended horizontally from the bafe to the apex; it is compofed of flefhy fafciculi, allowing the blood to penetrate in their intervals. A confiderable opening, by which the two cavities communicate, is found towards the right fide of the bafe of the ventricle, at the part where the feptum terminates. The parietes of the ventricle, of themfelves moderately thick, afford attachment to a multitude of flefhy fibres, giving additional

additional ftrength, but greatly diminifhing the cavity of the ventricle. Thefe fafciculi are moftly feparate from each other, allowing the blood to permeate between them as through a fieve; thus effecting the more perfect admixture between the portion arriving from the lungs and that from the body. The openings of the auricles are found clofe to each other, at the middle of the bafe of the heart, above the feptum. Each orifice is clofed by a femicircular valve of a membranous ftructure, the loofe edge of which correfponds to the auricle of the fame fide. The termination of the arteries is found in the right fide of the bafe of the organ; that belonging to the pulmonary artery is fituate towards the left and in the lower part, correfponding to the inferior cavity. On the left of the latter is found the opening of the left aorta, correfponding to the fame cavity, and placed oppofite to the opening which forms the communication between the fuperior and inferior cavity. The opening of the right aorta is found immediately behind the laft, and correfponds more particularly to the fuperior cavity, in which is received both the blood from the lungs and that from the body; the two portions united are projected partly into the right aorta and partly into the inferior cavity, and from thence into the left aorta and pulmonary artery.

In the fourth order of reptiles, the batracians, the heart prefents a ftructure the leaft complicated of the whole clafs. It confifts of a fingle auricle of a rounded figure, broader than the bafe of the organ, with its parietes ftrengthened by flefhy fafciculi. At the bafe of the auricle is the orifice of communication with the ventricle, which is fingle, having a fimple cavity, with flefhy columns, not feparated from each other. At its bafe is found the common trunk of the arteries, arifing by a fingle orifice, fituate more to the right and lower down in the ventricles than the opening of the auricles. The heart of the frog has been delineated by Swammerdam, Bibl. Natur. tab. 49; and by Roefel, Hiftor. Ranar.

Of the Blood-Veffels.—The diftribution of the blood-veffels in the four orders of reptiles is varied according to the ftructure of the heart, and many other circumftances in their organization. In the batracians the arrangement differs in the greateft degree from that of mammalia and birds. All the arteries arife by a fingle trunk; confequently there is but one opening in the heart. In the three other orders, there are at leaft two openings, frequently three, which give origin to as many diftinct trunks, one of which is deftined exclufively to the lungs.

Of the Arteries in the Chelonians.—The arteries of the body arife from the heart by a fingle or double trunk in different fpecies; thofe of the lungs by a fingle trunk. They are firmly connected together for a fhort diftance from their origin. The trunk of the pulmonary artery arifes on the left, lower down than that of the body. It quickly feparates into two branches, one of which proceeding to the right lung, turns from the left to the right, then advances forwards to arrive at the anterior part of the organ, where the infertion of the bronchus takes place. The other proceeds in a contrary direction, paffing acrofs the œfophagus, it arrives at the fummit of the left lung.

The trunk of the arteries of the body takes its origin at the right extremity of the bafe of the heart, and divides almoft immediately into two great branches, the right and left pofterior aortæ. When the trunk is double at its origin, they feparate, forming thefe two branches. The right aorta furnifhes, near its origin, another confiderable artery, which may be denominated the anterior aorta. This foon divides into two branches, each of which is again fubdivided into two others, the internal of which, the fmalleft, is the common carotid, and the external, the fubclavian or axillary artery. The common carotid proceeds by the fide of the neck, concealed by the mufcles going to the os hyoides, fending branches to the œfophagus and adjacent mufcles. It arrives at the head, to the parts of which it is ultimately diftributed, without dividing previoufly into two principal branches analogous to the carotids of mammalia. The fubclavian or axillary artery furnifhes nearly the fame branches as the arteries bearing the fame name in mammalia, with the exception that there is no branch correfponding to the inferior thyroid. The continuation of the trunk forms the brachial artery. The two pofterior aortæ proceed on each fide upwards and outwards; then bending backwards, they approximate again, and are connected by a communicating branch, which the left aorta gives to the right; nearly oppofite to the fifth dorfal vertebra.

The right aorta, previoufly to communicating with the left, furnifhes many arteries to the back or upper fhell, correfponding to the intercoftals. The left aorta furnifhes confiderable arteries to the vifcera of the abdomen, which confume great part of its blood. When the trunk arrives beyond the cardia, it divides into three branches; the firft, which is the fmalleft, furnifhes a branch to the œfophagus, and then is diftributed to the ftomach. It is analogous to the coronary ftomachic of mammalia. The fecond, almoft as confiderable as the trunk from which it proceeds, diftributes arteries to the inteftines, fpleen, pancreas, and liver, in the following manner. The hepatic artery is the firft given off on the right fide; it turns backwards and downwards to arrive at the liver, and divides into two branches, near the bafe of the vifcus, from one of which proceeds a fmall branch to the pancreas, and numerous others to the duodenum. The fecond branch is one of fmall fize, and is diftributed to the fecond turn which the colon makes to the right. It is the colica dextra. The third branch paffes from the right to the left, and diftributes its branches to the tranfverfe colon. It is the colica media. After having given off thefe branches, the trunk purfues a fhort courfe between the layers of the peritoneum, in a direction downwards and backwards. It then diftributes the following branches. The pancreatic, which paffes from behind forwards upon the left border of the pancreas. The fplenic, a very fmall artery, diftributed exclufively to the fpleen. A very confiderable branch, belonging to all the right part of the colon and cæcum. It is a fecond colica dextra. A fmall artery, which, after having given a branch to the cæcum, proceeds to anaftomofe with the next, the proper mefenteric artery, which is larger than any of the preceding, and ramifies in the mefentery of the fmall inteftine, to which it is ultimately diftributed. Laftly, the third branch, refulting from the divifion of the pofterior left aorta, the fecond in magnitude, proceeds obliquely to the right and backwards, and anaftomofing, as has been mentioned, with the right aorta, without furnifhing any branch. The common trunk, formed by their union, appears rather as a continuation of the right aorta; it extends along the vertebral column to the pelvis, giving off the following branches in its courfe. Five or fix fmall branches on each fide, correfponding to the intercoftal or lumbar arteries. The fpermatics. One or two branches on each fide to the kidnies. A fmall artery correfponding to the pofterior mefenteric, which is diftributed to the cloaca.

The common pofterior aortic trunk terminates by four branches, in the individuals belonging to the teftudo græca, which we have diffected. The firft on the left was the external iliac of that fide, then came the internal iliac of the fame ſame ſide, and oppoſite to it the primitive iliac of the right ſide. Between the two latter aroſe the artery of the tail, correſponding to the middle ſacral artery. The branches of the internal iliacs are very analogous to the ſame arteries in mammalia. The trunk divides into two branches; one ſending branches to the bladder and cloaca; the other dipping into the pelvis, and correſponding to the iſchiatic and poſterior iliac arteries. The external iliac proceeds forwards upon the border of the pelvis, furniſhes an analogous branch to the epigaſtric, from which ariſes the anterior iliac. The firſt deſcends upon the internal and inferior parietes of the upper ſhell, and paſſes in a direction from behind, forwards. A ſecond branch, which ariſes from the external iliac, oppoſite to the epigaſtric, deſcends along the anterior border of the pelvis, as far as the ſymphiſis of the pubis, and is loſt in the muſcles of that part. After having furniſhed theſe two arteries, the external iliac paſſes out of the pelvis, takes the name of crural artery, giving off firſt, the circumflex arteries, then the profunda, and in the reſt of its courſe is analogous to what it is found in mammalia.

The diſtribution of the principal arterial trunks in the ſaurians differs but little from that which has been deſcribed in the preceding orders.

In the crocodile there are three arterial trunks, each having a diſtinct opening in the ventricle, provided with two ſemi-lunar valves. The pulmonary artery, which ariſes from the cavity bearing the ſame name, is ſituate to the left, and ſomewhat ſuperiorly; the poſterior left aorta, which ariſes from the right and inferior cavity, and is ſituate between the pulmonary trunk and the next to be mentioned; the poſterior right aorta, correſponding to the ſuperior cavity. Theſe three trunks are connected together for a ſhort diſtance from their origin. From the latter proceed, in the firſt place, the trunk common to the ſubclavian and left carotid, which remains attached for ſome extent to the poſterior left aorta, then advances obliquely forwards, paſſes beneath the bronchus, and divides beyond that canal. Secondly, a ſimilar trunk for the ſame arteries on the right ſide. The poſterior aorta, after having given off theſe branches, turns in a direction, firſt from below upwards, then from before backwards, and divides in a direction obliquely inwards beneath the ſpinal column, without furniſhing any remarkable branch until it receives the communicating branch from the left aorta. This latter turns around the bronchus on its own ſide, and paſſes backwards and inwards in the ſame way as the preceding. After having paſſed the cardia, it divides into many branches, which proceed to the ſtomach, ſpleen, pancreas, and duodenum. Theſe receive the greateſt part of the blood of the trunk. The latter has no communication with the right aorta, but by an artery, the diameter of which is ſcarcely equal to a fourth part of the trunk from which it proceeds.

We have already alluded to the conſequences reſulting from this arrangement of the arteries, in the deſcription of the heart. All the other arteries derived ordinarily from the abdominal aorta, with the exception of the cæliac trunk, here take their origin from the right poſterior aorta. It is remarkable that the anterior meſenteric takes its origin at a very conſiderable diſtance from the cæliac trunk, or from the arteries ordinarily compoſing it; while, in the chelonians, it moſt frequently ariſes very near, or is even a branch derived from it. The ſplenic is alſo given off by the cæliac. After having paſſed through the ſubſtance of the ſpleen, from its anterior to its poſterior part, and diſtributed to its ſubſtance many ſmall branches which ariſe at a right angle from the trunk, it paſſes out almoſt as large as at its entrance, and proceeds to be diſtributed to the rectum, and the termination of the ſmall inteſtine; that branch of the ſplenic having the latter diſtribution, forms a conſiderable communication with the anterior meſenteric.

The pulmonary artery, very ſoon after its origin, divides into two branches, which proceed to the lungs, in the ſame manner as in the chelonians. Their diameter is nearly equal to that of the trunks formed by the carotids and ſubclavians on each ſide.

In the common iguana, which has the heart placed very far forwards in the cheſt, the arteries of the body have, in the ſame manner, two diſtinct trunks ariſing from the two cavities of the heart, although they are united at their origin. The left poſterior aorta does not furniſh any branch before it becomes united to the right. The latter gives origin to the carotids and ſubclavians, as in the crocodiles; but with this difference, that the latter do not ariſe from the ſame part as the former, but much farther backwards, on account of the heart being placed ſo much anteriorly.

In the lizards properly ſo called, the two aortæ advance forwards out of the cheſt; the right having firſt divided into three branches, the left without forming any diviſion. The latter turns backwards upon the ſides of the neck, to proceed afterwards along the vertebral column; and at the point where it takes a direction from before backwards, it receives the left branch of the right aorta, which forms a curvature in front of it. From its convexity ariſes the left carotid. The two other branches of the right aorta turn backwards, and unite in the ſame manner on the right ſide of the neck, forming two arches in front of each other. The carotid of the ſame ſide ariſes in a ſimilar manner from the anterior arch, formed by the middle branch. The ſubclavians ariſe from each aorta a little before their junction. We have ſeen that in the crocodiles and the common iguana, they are produced both by the right aorta. The trunk formed by the union of the two arteries, which unite ſpeedily after their origin from the heart, produces the different pairs of intercoſtal arteries in ſucceſſion. It gives off, near its commencement, an artery to the œſophagus; farther on, a ſmall artery which proceeds to the liver; and ſtill farther, an artery which quickly divides into two branches; the anterior of which diſtributes its ramifications to the ſtomach, ſpleen, pancreas, and duodenum. The poſterior belonging to the inteſtinal canal is properly the anterior meſenteric. From the trunk the following arteries next proceed: the lumbar, the ſpermatics, the poſterior meſenteric, which proceeds immediately to the rectum, the renal, which are among the laſt given off, ſince the kidnies are ſituate very far back in the abdominal cavity. Laſtly, it produces the iliacs and middle ſacral artery. The latter is of ſo conſiderable a ſize, that it may be regarded as a continuation of the aortic trunk, of which the iliacs appear only as branches. This circumſtance evidently depends on the great ſize of the tail, in compariſon with the extremities.

The diſtribution of the principal arterial trunks in the third order of reptiles, the *Ophidians*, becomes much ſimplified from the deficiency of extremities, and there being but a ſingle lung. The number of the trunks is the ſame; the relations between their openings in the heart have been already mentioned in the deſcription of that organ. The pulmonary artery aſcends and turns backwards upon the baſe of the heart, and ſpeedily arrives at the inferior ſurface of the lung, where it paſſes from before, backwards to the left of the vein. The right aorta aſcends on the ſame ſide, bends backwards, paſſes above the œſophagus, and obliquely backwards and inwards, to join itſelf to the left aorta, ſome diſtance beyond the point of the heart. It gives off, near its origin, ſome ſmall arteries, which proceed to an

orbicular

orbicular gland, placed in front of the bafe of the heart, likewife to another gland of a more confiderable fize and elongated form, fituate beneath the jugular. The trunk then furnifhes the common carotid, the only one exifting in this order of reptiles. It paffes obliquely to the left, and advances, by the fide of the left jugular, between the trachea and the œfophagus, and laftly beneath the latter. It fends a great number of ramifications to thefe organs, and divides near the head into many branches diftributed to the adjacent parts. Near to the vertebral column, the right aorta produces a confiderable branch correfponding to the vertebrals and fuperior intercoftals which proceeds along the fpine, fending to it branches, and wholly penetrating into it near the head. When the communication takes place between the right and left aorta, the diameter of the former is become very fmall, fo that the greateft part of the blood which it has received from the heart is diftributed to the parts in front of that vifcus: it is properly the anterior aorta. The left aorta afcends and turns backwards to the left, paffes beneath the œfophagus; then by the fide of and always beneath the lung, receiving the right aorta beyond the heart; and continuing to pafs in a direction backwards, it gives off branches correfponding to the intercoftals, likewife arteries to the vifcera. Thofe branches proceeding to the ftomach, pulmonary bladder, and liver, are detached fucceffively from the aorta, as it proceeds backwards; thus there is no cæliac trunk. Nearly oppofite to the pylorus. the aorta furnifhes the anterior mefenteric, which proceeds parallel to the inteftinal canal one half of its extent, fending to it branches. Farther backwards the inteftinal canal receives three other fmall branches in fucceffion, from the fame artery: as it paffes backwards, it alfo fends fimilar branches to the kidnies, ovaries, &c.; arrived at the lower part of the abdomen, it penetrates beneath the vertebræ of the tail and is loft in that part.

In the laft order of reptiles, the Batracians, the aorta, which proceeds from the bafe of the ventricle, foon divides into two branches, which feparate and purfue a very oblique direction from within, outwards and a little forwards. Each branch gives off a pulmonary artery, a common carotid, an axillary, a vertebral, and arteries correfponding to the intercoftals; then turning backwards, and approaching its fellow, it fpeedily becomes united to it. The trunk formed by their junction gives off, firft, the cæliac trunk, then all the other arteries which arife ordinarily from the abdominal aorta, prefenting nothing worthy of remark.

Of the Veins.—In the *Chelonians* there are two pofterior venæ cavæ, which pafs through the liver on each fide, and receive in their courfe numerous fmall hepatic veins. Immediately after their exit from the liver, they are joined by two anterior venæ cavæ, one on each fide, or by the common trunk of the jugular and fubclavian. They all terminate in the right auricle by an opening in the form of a fiffure, provided with two valves; they do not terminate in the cavity of the auricle, but in a receptacle communicating with it. The pulmonary veins united in a fingle trunk terminate in an analogous receptacle, which opens into the left auricle; around the borders of the opening, there is placed a flefhy valve in the form of a half moon.

In the *Saurians* and *Ophidians*, there is but one pofterior vena cava, and two anterior, that belonging to the left fide paffes acrofs, and above the heart, in a direction from left to right, and terminates in the common receptacle by the fide of the pofterior vena cava. This receptacle, fimilar to that found in the chelonians, has in the fame manner its entrance into the right auricle, in the form of a fiffure, and provided with two valves. In this order, likewife, the anterior venæ cavæ are more properly confidered as the jugulars. They have alfo a double azygos, one formed by the intercoftal veins in front of the heart, the other pofterior to it. They both join the right auricle by the fide of the right jugular. It appears that they are rendered neceffary by the fituation of the venæ cavæ, which is very remote from the vertebral column, and more inferiorly.

The pulmonary veins in the faurians are fimilar to thofe of the chelonians.

In the ophidian order there is only one, which terminates in the fame manner in the left auricle. Its volume exceeds that of the artery, which we have not obferved in the other reptiles.

In the batracians the veins have a diftribution fimilar to that of the arteries which refults from their terminating in a fingle auricle, in the fame way as the latter arife from a fingle ventricle. There are two anterior venæ cavæ which receive the blood from the head, neck, anterior extremities, and from the veins analogous to the external mammary, which are very confiderable, extending beneath the fkin to the groins, and likewife a pofterior vena cava, which receives the veins from the other parts, prefenting nothing worthy obfervation.

The blood-veffels of the tadpole are defcribed in the account of that creature in the divifion concerning the generative functions; and thofe of the proteus and firen, in the feparate defcription of thofe animals at the end of this article.

Phyfiology of the Circulating Organs.—The nature of the blood in reptiles, the points in which it differs from the correfponding fluid in other claffes, its difference in the various orders and genera, its relations to the food and to the fecretions and excretions, are fo many interefting topics of inquiry, on which we have abfolutely no information to offer. Chemiftry does not yet appear to be fufficiently advanced for the fuccefsful inveftigation of thefe and fimilar matters.

We may obferve, in the firft place, that the reptiles of thefe climates at leaft, poffefs, in comparifon with warm-blooded animals, a much fmaller quantity of blood in proportion to their fize: hence their mufcles are whiter, and fome of their vifcera, particularly the lungs, which are loaded and gorged with fuch a profufion of blood in the warm animals, prefent in this refpect an appearance altogether contrary in reptiles.

"I made an experiment," fays Blumenbach, "on the water falamander, (lacerta lacuftris, L.) of which I diffected twenty-four, adult, lively, recently taken in the early fpring, and weighing together $1\frac{1}{2}$ ounce, in order to meafure the quantity of blood they contained: I could preferve from the whole of the bodies of all, only two fcruples and a half. This fmall quantity of blood is to the whole body as $2\frac{1}{2}$ to 36; while in an adult and healthy man the proportions are calculated at 1 to 5. Haffelquift obferved the fame circumftance of the fmall quantity of blood in proportion to the body, in the crocodile of the Nile." Voyage dans le Levant & en Paleftine.

It is alfo remarkable, that the arterial blood of our reptiles differs in external appearance in the fmalleft degree, if at all, from the venous, fo that one can be diftinguifhed from the other only by the fituation and courfe of the veffels; while, on the contrary, the bright fcarlet arterial blood of the mammalia offers fo remarkable a contraft to the dark livid or purple venous fluid; unlefs when they have been for fome time in a warm bath or other warm medium, when it appears from the elegant experiments of Dr. Crawford,

ford, that the venous blood, becoming gradually lefs and lefs dark coloured, approaches more nearly to the vivid rednefs of the arterial ftream. (See Philof. Tranfact. v. 71. p. 487.) Haller obferved that there is no difference between the arterial and venous blood in the frog. (Oper. minor. v. 1. p. 183.) And Spallanzani noticed the fame fact in the falamander or water newt: "avutafi egualità di diametro, il colore del fangue venofo e fomigliantiffimo al colore del fangue arteriofo." De' fenomeni della circolazione, pag. 100. And again, "il fangue arteriofo in nulla differifce dal venofo, fia nel colore, fia nella denfità." P. 193.

In this circumftance reptiles refemble the fœtus of warm-blooded animals; in which, fo long as it remains immerfed in its uterine bath, we know that the arterial and venous bloods are of the fame colour.

Yet all animals of this clafs are not alike in this refpect. Accurate obfervers have afferted, that in the tortoife the venous blood is black, and the arterial crimfon, as in the warm-blooded claffes. (Caldefi, Offervazioni Anatomiche intorno alle Tartarughe, p. 60. Mery, Hift. de l'Acad. des Sci. de Paris, 1669. v. 2. p. 210.) This difference probably correfponds with the diverfity of ftructure obfervable in the refpiratory organs, which are calculated, in the different orders of reptiles, to admit of a more or lefs intimate expofure of the blood to the air in refpiration.

The colour of the blood varies in our amphibia according to the ftate of their nutritive functions: it is paler when they have fafted, of a deeper red when they have been well fed. If, under the latter circumftance, it be drawn from a vein, and expofed to the air, it exhibits a bright florid rednefs as it forms the coagulum.

The component elements of the blood of amphibia, confidered in a general way, feem nearly to refemble thofe of the warm-blooded animals, except that in the former, when examined alive, there are almoft always feen bubbles of air mixed with their purple ftream, performing, like the blood itfelf, the circulation, and dividing that fluid in the veffels into intervals, as the mercury is interrupted in a badly made thermometer. Redi and Perrault obferved this fact in tortoifes; Jacobæus in ferpents; Daudin in the green lizard, frog, and falamander (Hift. Nat. des Reptiles, Introd. p. 184.); and Blumenbach in the amphibia of Germany. Now, although in certain ftates the veins may be very turgid, and elaftic air may be found in them after death, nothing of this kind is ever known to take place in a healthy and ftrong individual. The air indeed is fuppofed in the mammalia to conftitute one-thirtieth of the blood, but it is fo diffolved, and fo intimately mixed in the vital ftream, that it can only be extricated and exhibited in its elaftic aerial form by artificial means.

The phenomena of the circulation are common on the whole to the reptiles with the warm-blooded animals, and are very familiar in the former, fince the wonderful circulating motion of the blood was not only firft actually feen and defcribed in frogs by the great Malpighi, but is alfo ftill examined to the prefent time in thofe animals. The branchiæ of the tadpole are very favourable objects for inveftigations of this kind.

As the circulation can be actually feen in thefe animals, we may inquire on this fubject, whether the globules of the blood, entering the minute veffels, can be really obferved to change their figure, and become oval inftead of fpherical. "In warm-blooded animals," fays Blumenbach, "I have never heard or read that any one has feen fuch a change; and I certainly have never feen, either in the incubated chick, in which the circulation of *warm* blood may be moft clearly and beautifully obferved, particularly on the fifth and following days, or in the frog or lizard, any oval globules: yet Reichel afferts that he has feen globules changed from fpherical to oval in the mefentery of the frog, and has given an elegant plate in illuftration of the fact. See Experimenta de Sanguine ejufque motu, fig. 3." Blumenb. Specimen Phyfiol. p. 10. He doubts, however, whether this change can be confidered as a natural occurrence in the healthy circulation, or ought to be referred to the difturbance naturally following the fufferings of the animal.

The motions of the heart, confifting in our amphibia of a fingle auricle and ventricle, agree in the alternate contractions and relaxations of thofe parts, with the analogous fucceffion of fyftolic and diaftolic changes obfervable in the double auricles and ventricles of the warm-blooded claffes.

A queftion was formerly raifed, concerning this fyftole or contraction, whether the ventricles are really fhortened, or experience merely a diminution of diameter? The former, fays Blumenbach, has now been proved by the moft careful obfervations both in cold and warm-blooded animals; he adds, that he has never feen it demonftrated more clearly, and beyond every fufpicion of inaccuracy or miftake, than in the common fnake (coluber natrix), in fpecimens of which, two yards long, from the woods of Germany, he has obferved, and frequently demonftrated, a fhortening of the ventricle equal to two lines. Blumenbach ftates further, that the ventricle is completely emptied in its fyftole, not the leaft drop of blood flowing back into it from the aorta, in the fnake, frog, and toad, and alfo in the incubated chicken. But he does not venture to decide, whether the fame thing occurs in man and the other mammalia, or whether the femilunar valves may intercept fome drops of blood, which thus are made to flow back into the ventricle.

Reproduction.—As the nutrition and growth of parts, in the healthy ftate, are among the moft important functions of the blood-veffels, fo the reparation of injury, and the reftoration of what is mutilated, conftitute another very ftriking inftance of their powers, and a very impreffive example of thofe prerogatives, which belong exclufively to living organized beings. Although this power of reproduction, taken in its moft extenfive acceptation, cannot be faid to be withheld entirely from any animal, feveral genera of reptiles poffefs it in a more remarkable degree than any of the other vertebral claffes. There is an interefting account in the Memoirs de l'Acad. des Sciences de Paris, 1686, particularly of the reftoration of the tail of lizards. Spallanzani, Bonnet, and Blumenbach, have employed themfelves in refearches on this fubject. The former firft called the attention of the public to it in his "Prodromo di un' Opera da imprimerfi fopra le Riproduzioni Animali." Bonnet publifhed his memoir on the reproduction of the limbs of the water newt in the Journal de Phyfique, 1777. His enquiries were again publifhed in his "Œuvres d'Hiftoire Naturelle," t. 5. and there are three memoirs by him on the fubject, tranflated into Englifh, in Spallanzani's "Tracts on the Natural Hiftory of Animals and Vegetables," v. ii. The experiments of Blumenbach are contained in his "Specimen Phyfiologiæ comparatæ." The experiments have been made chiefly with the water newt; on the lacerta agilis of the terreftrial kind, fee P. T. Hartmann, dubia de generatione viviparorum ex ovo, p. 26; refpecting the lizards of the Antilles, fee Oldendorp Gefchichte der Caraibifchen Miffion, p. 97.

"It might be fuppofed," fays Bonnet, "that the amputation of the limbs is moft painful, and that the animals would fuffer long and feverely from it; however, one of my obfervations apparently infers the reverfe. I cut the left hand

hand and the right foot off a large newt ; and a ſtream of blood, as thick as a hog's briſtle, continued ſpouting out nearly two minutes without intermiſſion. Not only did the animal ſeem not in the leaſt enfeebled by the loſs of blood, but, in ſcarcely a quarter of an hour, to my great ſurpriſe, it ſwallowed two earth-worms." Spallanzani's Tracts, v. ii. p. 367.

The following narrative is extracted as a ſpecimen of Bonnet's experiments. "On the 6th of June I cut off the right arm and left leg of a large newt cloſe to the body. (It ſeems from the accompanying figure that the ſections paſſed through the femur and humerus reſpectively.) A ſtream of florid blood ſpouted a minute and a half from each wound ; however, the veſſels ſoon cloſed, and the newt was apparently as well as thoſe unmutilated. But it will eaſily occur, that it did not ſwim with equal facility. When about a month had elapſed, I began to perceive a papilla, of a violet grey colour, near the edge of the trunk or ſection. This was the origin of a new arm and leg, which gradually increaſed, and were quite perceptible, although ſtill very ſmall, on the 14th of July. The two papillæ grew more in length than in thickneſs : they became minute ſtumps, and on the 1ſt of Auguſt were two lines long. A kind of cleft hardly perceptible announces the appearance of two toes : no cleft appears on the originating arm. The new parts were very diſtinguiſhable from the old by their lighter colour. The two toes were eaſily recogniſed on the ſeventh : they were real miniatures, and truly moſt minute. The ſtump of the arm had increaſed, but there was no indication of fingers.

"It is pleaſing to obſerve the little hand fully unfolding, while only three fingers of unequal length are viſible : the middle one is the longeſt. The arm has made no ſenſible progreſs. The new foot had four toes alſo of unequal length ; the firſt and ſecond of which are longeſt ; the other two only begin to appear ; the fourth is ſcarcely perceptible. Evolution advanced every day. The regenerated members began to deepen in colour, ſo that the line, diſcriminating the old parts from the new, was no longer ſo conſpicuous ; but the black ſpecks on the toes of unmutilated newts were ſtill imperceptible. On the 22d of Auguſt four well-ſhaped fingers were already on the hand ; but only four toes out of the five which the foot regenerates ; and they all have to acquire more ſize, conſiſtence, and colour. I continued my obſervations on the daily evolutions of the members ; and the following were their dimenſions in length on the 30th of September.

Old Members.			New Members.		
Arm	-	4 lines.	Arm	-	2½ lines.
Cubit	-	3½	Cubit	-	2½
Thigh	-	3	Thigh	-	2⅔
Leg	-	4	Leg	-	2¼
Longeſt finger		3⅔	Longeſt finger		1½
Longeſt toe	-	4½	Longeſt toe	-	1⅓

Even in the beginning of October, the fifth toe of the new foot was not viſible." Lib. cit. 372, et ſeq.

There is a kind of ſemi-tranſparency in the reproduced parts, which the original members have not. This continues long, and changes ſlowly as the reproductions colour. The tranſparency is evidently greater on the edges of the fingers than elſewhere ; if examined with a magnifier they ſeem incloſed in a fine diaphanous envelope : but nothing of this is evident in the old fingers. (P. 376.) "It is incredible how long the new fingers require to attain the ſize of the old. I have had newts, whoſe fingers, in thirteen months and more, were not as large as thoſe of unmutilated members." (P. 393.) "When the tails of large newts were amputated near their origin, the whole died in a certain time. If the part be cut off about its middle, reproduction will follow. A tail was cut on the 11th of July, and on the 14th of Auguſt, the reproduced part was about three lines and a half long, and four and a half in diameter at the baſe. The new portion was ten lines in length on the 20th of September, and ſhaped exactly like the tail of a newt. I could obſerve no difference between the motions of this regenerated tail, and thoſe of tails unmutilated. On the 8th of October the regenerated part had a peculiar tranſparency, wanting in the reſt of the tail." P. 381, et ſeq.

"The fingers and toes are not evolved in the ſame proportion as the arm and leg. Now, when I write this, on the 10th of October, the new arm and leg of the newt, mutilated on the 6th of June, have nearly attained the ſize of the original members, while the regenerated fingers and toes have not acquired half their natural ſize ; yet they are perfectly well formed, and execute all their functions." P. 390.

Blumenbach found that the true ſalamander (lacerta ſalamandra) poſſeſſes the ſame reproductive power as the water newt (lacerta lacuſtris) : that a third part of the tail, or a toe, would be perfectly but very ſlowly reproduced, and remained even at the end of a year conſiderably inferior in ſize to that of the original parts. Specimen, p. 32.

Bonnet made other experiments to determine whether reproduced members poſſeſs the ſame powers of reproduction as thoſe amputated. He cut off an arm and a thigh of a large newt on the 2d of June : as ſoon as the hand and foot were viſible, he cut them off, and they were renewed : he repeated this four times, the laſt operation being on the 13th of October, and the parts were each time reſtored. P. 394, et ſeq.

He diſlocated the arms of one and the thighs of another newt, ſo that the members immediately after were pendent, as if dead, the animal having no power over them. On the following evening each newt moved the disjointed limbs with a liberty and facility which announced that nature had already repaired the diſorder. P. 431.

The moſt ſurpriſing fact in Bonnet's Memoir is the reproduction of the entire eye. "With a ſcalpel," ſays he, "I extracted the right eye of a large newt on the 13th of September, 1779 ; but I did not obtain the globe without much injury to the tunics. A deep bloody wound in the ſocket of the eye was the conſequence of this cruel operation. And the reader will not be ſurpriſed if I hardly expected any thing from it, and that the newt would probably remain blind for ever. How great was my aſtoniſhment, therefore, when, on the 31ſt of May, 1780, I ſaw a new eye formed by nature. The iris and cornea were already well ſhaped, but the latter wanted its peculiar tranſparency, which is very conſiderable in theſe animals. The reſtoration was complete on the 1ſt of September ; the cornea being tranſparent, and the iris having acquired its yellow gilded colour. On the 8th of November 1780, it differed from the other eye only in being a little ſmaller, and in the iris, or golden circle, going only half round the ball." P. 432, et ſeq.

"I repeated," ſays Blumenbach, "the experiments of the celebrated Bonnet, concerning the reproduction of the eye in the water newt. I cut out the whole globe, at the inſertion of the optic nerve, in three inſtances, in neither of which was the organ reproduced : but a white and firm fungus, ſhooting from the cut end of the nerve, gradually filled the orbit, the animals themſelves becoming affected with a kind of dropſical ſwelling, and dying in a few

few months. Inftructed by thefe failures, I proceeded to operate in a different way on a fourth animal, in May 1784. I firft divided the cornea, to let out the lens and other humours, and then cut away the remaining empty and collapfed coats, leaving a fmall portion of the common coverings of the bulb, which, from a careful examination in water with a glafs of the parts removed, I judge to have been fcarcely equal to one-fifth of the whole globe. In the following months the whole orbit feemed clofed by the approximated eye-lids, which, however, began to feparate in the fixth month after the operation, and thus difclofed a new little bulb fpringing up from the bottom of the orbit. This new globe was ftill much fmaller than the other in April 1785, when the animal died accidentally, though in other refpects it was moft perfect, exhibiting the golden iris with its regular pupillar aperture behind the cornea, all which points are clearly diftinguifhable in the preparation which I preferve." Specimen, p. 31.

"On comparing," fays the author laft quoted, "the facts juft detailed with the very limited and much lefs perfect reproduction obfervable in warm-blooded animals, we fhall become fenfible of the wide difference between them and the amphibia. I am daily more and more convinced, that no parts are reproduced in man and the other mammalia, except fuch as are compofed merely of cellular fubftance, and enjoy no other kind of vital power except common contractility; and I cannot find fufficient proof that the irritable mufcular fibre, the fenfible nervous medulla, or thofe parenchymata which are endowed with a peculiar modification of vitality, have ever been truly reproduced in a warm-blooded animal." Ibid. p. 32.

Tenacity of Life.—This fubject is fo far analogous to that which we have juft confidered, that we pafs naturally from the view of the facts, in which the furprifing reproductive powers of the clafs is evidenced, to the no lefs aftonifhing examples of their very hardy vitality; of the energy and permanence of their vital forces, both in individual parts, and in the body at large.

The amputated tails of water newts, and the divided fragments of the blind-worm (anguis fragilis), exhibit very lively motions for ten hours and more. The heart of a frog or ferpent continues to palpitate on irritation many hours after its feparation from the body; and the limbs of frogs are excitable by the Galvanic influence for a long time. Some reptiles, as the ferpents and teftudines, can open and fhut the mouth long after the head has been fevered from the trunk. General Gage informed Blumenbach that he had feen the amputated head of a rattlefnake bite long after its feparation: and another Britifh officer ftated to him that when he put a ftick between the jaws of an American turtle, the fecond day after decapitation, it was firmly held.

The fame energy of the vital force in the parts, and the independence of one clafs of functions on another, in the amphibia, are further evinced by many well known facts; the limbs of turtles have moved for eleven days, nay, on the thirteenth day after decapitation (Güldenftaedt, Theoria virium corp. hum. primitivarum, p. 74.); and a rattlefnake lived fome days after the fkin had been removed, and moft of the vifcera taken away. Tyfon, in Philofophical Tranfactions, N° 144.

In the beginning of November, Redi opened the fkull of a land tortoife, and removed the whole brain. The animal did not feem to fuffer, it moved about as before, but groping its way; for the eyes foon fhut after lofing the brain, and never opened again, a flefhy integument formed, which covered the opening of the fkull, and in this ftate the animal lived till May. Spallanzani deprived four frogs of the brain; two lived till the fifth day. He alfo deprived three newts of the brain; they fuffered violent convulfions; their eyes clofed, they hardly moved from one place to another; and expired about the middle of the third day. He cut the heart out of three newts; they took to flight, leapt, fwam, and executed the fame functions as before; however, all died in forty-eight hours. Four frogs, deprived of the heart, kept their eyes open, and preferved the ufe of their limbs. They furvived thirty-fix hours. Spallanzani's Tracts, Introduction, p. 45.

Captain Cook met with a turtle, in which there was a wooden harpoon about fifteen inches long, and barbed, between the fhoulders. The opening by which it had entered was quite healed.

Redi and Boyle faw fome figns of life in ferpents after they had been twenty-four hours in vacuo. And they will live more than four hours in fpirits of wine. See Daudin, v. 6. p. 100; and v. 1. p. 270.

In our account of the phyfiology of the digeftive organs, we have already noticed the fingular power which reptiles poffefs of remaining for fuch long periods without food. They are equally remarkable for being able to bear, permanently, confiderable degrees of heat and cold. Not only are moft of the Clafs inhabitants of the warmeft regions, but fome of them, like fome fifhes, are known to live in warm fprings, inhabiting them fpontaneoufly, and appearing to be healthy. (See Cocchi in Spallanzani, Opufcoli di fifica animale e vegetabile, v. 1. p. 46.) They live in the warm fprings of Pifa, which rife to 37° of Reaumur, 115° of Fahr.

"Befides a hoft of fufpicious narratives," fays Blumenbach, "of newts, and other amphibia, which have lived for a confiderable time in the human body, there are many unexceptionable and indubitable examples of this remarkable phenomenon." See the narrative of Th. Reinefius, a moft refpectable authority, concerning a girl of Altenburg, in Bartholin, Act. Havnienf. v. 2. p. 110; Harder, Apiar. obfervat. p. 89; I. R. Zwinger in Act. Helvet. v. 1. p. 22; Hift. de l'Acad. des Sciences de Berlin, 1770, p. 40; a mafs of citations in Jacobæus de ranis et lacertis, p. 12; Paulini de Bufone, p. 38; I. Helwig Obferv. p. 249 and 272; Kundmann Promptuarium, p. 108; alfo Act. Natur. Curiof.; Collectan. Vratiflavienf. et Commerc. Literar. Noric. &c. Thefe facts are not fo remarkable on account of the degree of heat to which the animal is expofed, as from the other concomitant circumftances. We muft obferve, however, that thefe animals inhabited the ftomach fo long as they continued alive, while the individuals troubled by thefe unufual guefts were led, by their fuffering, to drink copioufly of water, and thus in a manner fupplied the newts with their natural element.

"Reptiles have the power of bearing intenfe cold as well as great heat. I one morning found a tree-frog, which I had kept for fome time, in confequence of a froft fuddenly fet in the preceding night fo as to reduce the thermometer to 30° Fahr., completely inclofed in a cake of ice, like infects in amber; of courfe it was motionlefs, the eye-lids fhut, &c. As the ice melted, the animal recovered, firft moving its hind legs, when they were difengaged; the head and trunk ftill being moft firmly detained; when the folution was complete, the whole animal was reftored, feemed as well as before, and furvived a long time. Du Fay attefts the fame circumftance concerning water newts; Mém. de l'Acad. des Sciences de Paris, 1729, p. 144. The amphibia are expofed to be frozen in their winter fleep; but we are the lefs

 furprifed

furprifed at the occurrence, becaufe all the functions are either entirely fufpended, or moft languidly performed." Specimen, p. 10.

Organs of Refpiration.—After defcribing the heart, and viewing the phenomena of the circulation, we proceed to the lungs, which are not only moft important parts in the economy of all animals that poffefs blood, but conftitute, in the peculiarity of their ftructure and functions, the moft ftriking marks of diftinction between reptiles and warm-blooded animals.

All reptiles breathe by means of lungs, which in their bulk confiderably exceed thofe of the mammalia, while the latter are as far fuperior in the abundance of their vafcular ramifications, and the wonderful minutenefs of their internal fubdivifions. Thefe large, but loofe and rare veficular lungs, are contained, not in a particular cavity, feparated from the abdomen by a diaphragm, but, with the other vifcera, in a general cavity of the body. Hence the mode of refpiration is as different from that of the mammalia, as the texture of the organ.

To the general pofition, that reptiles breathe by means of lungs, there is an exception in the batracian order; in fome of which (the proteus and firen) there are branchial appendages or gills, as well as lungs; while in the firft ftate (the tadpole) of others, there is a fimilar conjunction of thefe two modifications of refpiratory apparatus. See the anatomy of the tadpole, in the account of the generative organs, and that of the firen and proteus, at the end of this article.

The Air-tubes.—The trachea is not divided into bronchi in the ophidian order, which have a fingle lung; neither does this divifion take place in the green lizard (lacerta agilis), whofe trachea, having reached the united anterior extremities of the two lungs, opens into each by a large orifice: but it is found in almoft all the other animals of this clafs. The divifion is effected very early in the chelonians, which have confequently a very fhort trachea, and long bronchi; more particularly becaufe the latter, inftead of entering the lungs directly, firft make a turn in the cheft. The trachea is divided much later in the crocodile, where the tube is bent from behind forwards, divided into bronchi, which alfo run forwards, and then turn from before backwards, remaining for fome time joined to each other. The bronchi are extremely fhort in moft other reptiles: they begin, in the batracians, immediately below the larynx.

Reaching the lungs, the bronchi generally terminate abruptly by one or more large orifices, which open into the cavities of thefe vifcera. This is what occurs in the ophidians; but in the chelonians and the crocodile, each bronchus is continued into the interior of its lung, before it terminates. They are continued, in the teftudo græca, into the moft remote part of the lung, without undergoing any fenfible change of diameter; and they communicate with the large cells compofing thefe vifcera, by ten or twelve wide orifices, of which the outlines are circular, like the commencement of canals. In the turtles, each bronchus penetrates in like manner to the fartheft part of the lung, but gradually diminifhing in diameter. Their fides are pierced with numerous holes, opening into the pulmonary cells.

The relative fize of the trachea and bronchi does not exceed what we obferve in the mammalia and birds, except in the ophidians, where the diameter of the former is very confiderable. Thefe air-tubes never exhibit any inequalities, fuch as are feen in birds.

They are generally compofed of complete cartilaginous rings, and confequently are little fufceptible of changes in fize. We muft, however, except the crocodile, in which animal the front end of the trachea prefents, on its upper furface, a membranous interval, which is wider the nearer we come to the larynx; (fee Humboldt Recueil d'Obfervations, &c. tom. i. p. 11. of the crocodile of the Orinoco; and Geoffroy in Annales du Mufeum, tom. ii. of the Nilotic fpecies); the cameleon, where the annuli are incomplete in the laft portion of the trachea, and at its bifurcation; and the ophidians, in whom the trachea poffeffes cartilages only in one third of its circumference. Thefe cartilages are alfo vifible for a fhort fpace along the front end of the lung, in a groove of its inferior furface, containing alfo the pulmonary vein. The trachea, however, ceafes fuddenly on touching the lung, and dilates immediately to form its fac.

In thofe reptiles which have bronchi running throughout the length of the lungs, the portion of the tube, contained in thefe vifcera, has only imperfect and irregular pieces of cartilage, which neverthelefs furround its circumference. They are more thinly fcattered in the turtles, in proportion as we obferve them farther back in the lung.

This cartilaginous ftructure of the air-tubes (the trachea and bronchi) of reptiles, renders them very incapable of changing their diameter. They feem entirely deftitute of tranfverfe mufcular fibres; nor do we perceive any longitudinal ones to diminifh their length. The membranous trachea of the ophidians, poffeffing cartilages only in the inferior third of its circumference, feems equally deftitute of mufcular fibres. On this membrane we difcover a fine white and opaque net-work, which is continued into the interior of the lung, where its mefhes, as we fhall fee, border the cells, and are formed of ftronger threads, apparently of a tendinous ftructure, and perhaps capable of contraction.

Veficular Structure of the Lungs.—We have mentioned that the lungs of reptiles are very large: they are immenfe in the teftudines and cameleon, and are even confiderable in the native amphibia of thefe climates, if you compare their relative bulk to that which they poffefs in warm-blooded animals. We have juft feen that the bronchi do not divide, that they do not ufually enter the lungs, but terminate abruptly by one or more large orifices, as foon as they have reached thefe vifcera. In the batracians and faurians, the lungs form two facs, varying confiderably in their form and relative fize, and having their internal furface divided by membranous plates into polygonal cells, in which other fmaller plates form more minute divifions. They have been juftly enough compared by Blumenbach to the reticulated ftructure, in the fecond ftomach of ruminating animals. Thefe cells are more numerous, fmaller, and deeper in the anterior part of the fac: they become more open towards the pofterior part; and when the latter terminates in one or more appendages, we fee only a net-work, with loofe and extremely fine mefhes. Afterwards the parietes of the pulmonary fac are quite fimple, and without any divifion. Such is the ftructure in the appendices which terminate pofteriorly the lungs of the cameleon, and the agame or lacerta marmorata; and of the great bladder in which the fingle lung of the ophidian order ends.

The lungs of the falamander, the proteus, and firen, form alfo fimple facs without any divifion.

"In frogs and toads," fays Blumenbach, "the lungs are made up of polyhedric and large cells: the fame ftructure is obferved in the lacerta agilis and falamander. They form an oblong bladder in the aquatic lacerta (water newts). The lung of the coluber natrix forms a fingle bag of large fize, hollow throughout; and the fame ftructure feems, from the reports of anatomifts, to exift in other ferpents. (See Coiter Obf. Anat. Chir. p. 126. Charas Nouvelles

Nouvelles Obf. fur la Vipère, p. 39. Tyfon in Phil. Tranf. N° 144. p. 30. tab. 1. fig. 1. tab. 2. fig. 4. Seba Thefaur. vol. ii. tab. 109. fig. 1—5.) The pulmonary bag of this coluber exceeds a Paris foot in length. Rather more than the anterior half has thick fides, with an elegantly reticulated internal furface, refembling in its general habit that of the internal furface of the fecond ftomach of the ruminating mammalia. The remaining pofterior portion is a fimple thin membranous bladder." Specimen, p. 12.

The ftructure is rather more complicated in the chelonian order. Each of the openings of the bronchus, which we have ftated to be about ten or twelve in the teftudo græca, is the entrance of a particular fac, the fides of which are compofed of polygonal cells, in which there are ftill fmaller ones. Each of thefe cells is bordered by whitifh and as it were tendinous chords, which appear defigned to fupport their fides, and fix the facs to the orifices of the bronchus. The facs or principal cells are much fmaller, and more numerous, in the turtles, and correfpond to the numerous orifices with which the bronchus is pierced. We fee alfo the cords forming and fupporting the cells, and giving to the lungs of thofe animals the appearance of a cavernous tiffue.

The form and fize of the pulmonary cells may be fomewhat different in the crocodile, but their effential ftructure is the fame. In this refpect the crocodiles depart from the lizards, and approach the turtle and tortoife. Geoffroy in Annales du Mufeum, vol. ii. p. 46.

How different a notion do thefe details convey to us, of the ftructure of the lungs in reptiles, from that which they poffefs in the warm-blooded claffes! Although they may be defcribed in the latter as cellular, fpongy, and light, yet, when compared to the fame organs in the former clafs, they are vaftly more compact, made up throughout of an infinite number of ramified air-tubes, and of countlefs moft minute bronchial cells connected to them, united and interwoven with common cellular tiffue. Hence, if we compare any mammiferous animal with a reptile of the fame fize, as the vefpertilio murinus with the rana bombina, the lungs of the latter are indeed the largeft, but are beyond all comparifon inferior to thofe of the former in the very inconfiderable number of their cells.

As the lungs of warm-blooded animals fo wonderfully furpafs thofe of reptiles, in the minutenefs and number of their cells; fo they ftill farther excel them in the aftonifhing abundance of their blood-veffels. The fimple appearance of the organs, without any anatomical preparation, is fufficient to fhew this fact; and microfcopical examination, after fuccefsful injection, fully confirms it. For, although the lungs of the amphibia exhibit their denfe vafcular networks, beautifully painting the fides of the cells, thefe are not to be compared to the number and fubtilty of the ramifications, eluding even the affifted eye, which every where fill up the lungs of warm-blooded animals.

Since, in the mammalia and birds, all the blood of the body muft pafs through the lungs, before it can return again to the organs, it was neceffary to have a large number of veffels for its conveyance, and a furface for their expanfion, both extenfive on account of their number, and the neceffity of expofing the blood in minute portions to the air, and yet confined as much as poffible to one fpot, that its bulk might not be inconvenient. Thus we explain that inextricable tiffue of blood and air-veffels, and fmall veficles or cells, which compofe the lungs of mammalia and birds. All thefe circumftances are different in reptiles. If we may judge from the diameter of the pulmonary arteries, they receive at moft a third of the circulating mafs, and fometimes much lefs. It is not neceffary that this blood fhould pafs back again through the lungs to return to the body: it may proceed by another route, as we have explained in the account of the circulating organs; becaufe it does not require to be fo frequently fubmitted to the action of the air, as in the two claffes mentioned above. Hence have refulted the two great differences already pointed out between the lungs of the warm-blooded claffes and of reptiles; differences which are obvioufly related to each other, the numerous vafcular ramifications requiring numerous cells and vifcera.

The pulmonary ferve alfo as bronchial veffels in reptiles; at leaft we find no arteries or veins of the latter defcription. The arterial and venous bloods are mixed in the heart; and the fame that goes to the lungs is conveyed to all other parts of the body for their fupply.

Yet the pulmonary are not the only arteries conveying blood to the lungs in reptiles: the ferpents, at leaft, offer an exception. The ramifications of the pulmonary artery are confined to that part of the lung, which has a reticulated internal furface. The pofterior part of the organ, compofing the fimple membranous bag, receives blood only from the arteries of the body. A part of the twigs that fupply it comes from the branches of the pofterior aorta, which are alfo diftributed on the ftomach. Other very minute ones are detached fucceffively from the vertebral column. The veins correfponding to thefe arteries pour their blood into the vena cava. In this fingular ftructure, we find a part of the lung executing the office of the cells of birds: and a portion of the blood, very fmall indeed, contained in the arteries of the body, is again fubmitted to the action of the air.

That portion of the general ferous membrane which covers the lung has nothing peculiar in reptiles.

The form and bulk of the organs vary much more in this clafs, than in the mammalia and birds. Both are determined in the mammalia by the cavity of the thorax; in birds, by the peritoneal cells, which limit them on one fide, and by the ribs, which cover them on the other. In reptiles, on the contrary, nothing feems to limit their developement, nor to give them a peculiar figure. Commonly they form oval bags, which extend in the chelonians along the back to the pelvis, above all the vifcera; they are lefs extenfive in the faurians and batracians. The ferpents have a fingle very long lung, prolonged over the œfophagus, ftomach, and liver, beyond the latter parts. In this fituation it is expofed to preffure every time the animal fwallows a large prey. Does this check the pulmonary circulation, and contribute to the torpor which ferpents experience at thefe times?

In the cameleon, and the agame marmorata, each pulmonary fac is very extenfive. They are divided into large conical appendices, prolonged as far as the pelvis, placed among the vifcera, and capable of holding fo much air, as to increafe the animals' bulk confiderably when they are diftended. The lungs of the firen lacertina are two long cylindrical facs, continued to the end of the abdominal cavity. In the larvæ of the falamander, there is a fmall oval cavity, opening by a narrow canal in the fauces.

Branchiæ or Gills.—The firft orders of reptiles (the chelonians, faurians, and ophidians) never poffefs this kind of refpiratory organ: they have only lungs. The batracians in their firft ftate, and the proteus and firen during life, have both lungs and branchiæ, or rather branchial appendages (appendices fimbriati). See the anatomy of the tadpole, and that of the proteus and firen, at the end of this article.

Expanfive Power of the Lungs.—" A fingular power," fays Blumenbach, " characterifes thefe vifcera in reptiles, and is is a point, in which they exceed those of the human subject, and of the other mammalia; namely, a particular kind of tone, or energy, by virtue of which, even when the chest is opened, and they are exposed to the external air, they are still distended and support themselves, while those of the mammalia, when the sternum is removed, and the thoracic cavities exposed, allow the air to rush out, and collapse. (See Morgagni Adversar. Anat. 5, 29, and the elegant experiments on the tortoise by the Parisian academicians; Hist. des Animaux, part ii. p. 194.) It is even asserted, that when the lung is compressed in a tortoise opened alive, it has the power of distending itself again. (Coiter Obs. Anat. Chir. p. 127.) A tortoise, from whom the lower shell had been removed, the thorax consequently being opened, and the lungs exposed to the air, survived for seven days. (Hist. des Animaux, just quoted.) The cause of these phenomena can only be found in the peculiar vital properties of the lungs; as it cannot be referred to contractility, irritability, or nervous influence. I have never been able to detect, in the lungs of amphibia, any more appearance of truly muscular texture, than in those of the mammalia, to which a modern author has too liberally assigned irritability. (Varnier in Hist. de la Soc. de Médécine, 1779.) The design of this peculiar vitality in the lungs of amphibia will appear very obvious, when we consider that it exists in animals who have a very imperfect bony thorax, or none at all, or one in great measure incapable of motion. Such is the case with frogs and toads, who are entirely destitute of ribs; with nearly all the tortoises and turtles (excepting, perhaps, a few of the soft species), in whom the whole coverings of the trunk are immoveable, so that neither the thorax, nor the abdominal muscles, can execute those motions in respiration, which they perform in warm-blooded animals."

Mechanism of Respiration.—In this, as well as in other points, the several orders of reptiles differ from each other. The chelonians, whose ribs are in the form of large osseous plates, consolidated to each other, and motionless, are, in effect, like the batracians, some of which have no ribs at all, while in others these bones are too short, and too little susceptible of motion, to be capable of assisting in the process of respiration. In all these animals, then, we can no longer regard these bones as the principal agents of the respiratory function. They also want the diaphragm, like all other reptiles. Consequently the mechanism of respiration differs in them, in its essential points, from that described in the article Lungs, which belongs to the whole class of mammalia, where the respiratory organs, inclosed in a peculiar cavity, follow all the motions of that cavity.

In fact, it is now well ascertained, that the batracian reptiles *swallow* air into their lungs. They close the mouth, and dilate the throat, when the external air, rushing through the nostrils, fills the empty space. The sterno-hyoidei, carrying the os hyoides downwards and backwards, are the great agents in this dilatation of the throat: the coraco-hyoidei assist them. When the former muscles are cut, respiration ceases. The elevation of the os hyoides, principally by the stylo-hyoidei, contracts the cavity of the throat, and drives the air into the lungs. The escape of this air from the throat by the nose is, no doubt, says Cuvier, prevented by a valve; but no such structure has been demonstrated. The action of the abdominal muscles, and perhaps a contractile power of the lungs themselves, expel the air from these viscera in expiration. Townson, who has investigated this subject most attentively (see his Observationes Physiologicæ de Respiratione Amphibiorum, 8vo. Vienna, 1798, with figures; also translated into English in his "Tracts,") observes, that he does not know whether the muscles extending from the glottis to the pubes should be called oblique or not. They surround the lungs in their whole extent, and have a considerable compressive force. They probably consist of different muscles; their fibres extend more or less transversely, and are therefore well calculated to produce the effect he has assigned to them. He states that he has always seen the frog's lungs collapse when the glottis was opened, whether the animal was dead or alive.

If the muscles and the membrane of the throat are removed, leaving only the sterno-hyoidei, the motions of the os hyoides, which take place in respiration, are continued, although respiration itself is destroyed. The latter effect is a consequence of the destruction of the throat; no cavity can now be formed to receive the air, which the animal swallows in breathing. The os hyoides, however, is alternately depressed and elevated, and the glottis continues to open and shut, but the lungs are permanently collapsed. If all the muscles employed in moving the os hyoides are cut, the glottis, whose muscles are entire, is opened and closed. In the same way, when warm-blooded animals have received a large wound in the chest, they make vain efforts to breathe, and to get rid of the painful sensation of suffocation.

It will appear, from the preceding description, that the frog's mouth must be shut when he breathes: and this is so strictly necessary, that the animal perishes from suffocation, if his mouth be kept open. Herholdt and Rafn asserted this in a communication to the Academy of Sciences at Copenhagen, and the point has been verified by Cuvier and Duméril. See Bulletin de la Société Philomatique, N° 30, an. 7. p. 43.

The same mechanism is employed in the chelonians. Deglutition is the only means they can employ for introducing air into their lungs. Having the mouth closed, they alternately contract and dilate the throat, like the batracians, and by the same powers. The air is expelled from the lungs by two pairs of muscles, analogous to the abdominal muscles. These fill the posterior interval between the sternum and the back shell, in which the posterior extremities are folded when at rest. We perceive, at this part, in the chelonians, those motions of contraction and dilatation, which are observed over the whole abdomen in the mammalia.

The first, or outer pair, correspond to the external oblique muscles: it is attached to the whole anterior edge of the pelvis, to the back and front shell, and is extended in the whole posterior interval of these parts. The internal muscle consists of transverse fibres, attached above to the posterior half of the back shell, near the vertebræ, descending on the outside of the viscera, inclosing them, and terminating below in a middle aponeurosis. The latter passes partly under the bladder, and will serve to evacuate that organ when the muscles contract. They compress immediately only a small portion of the lungs; but they press strongly on the abdominal viscera, and through the latter on the lungs, so as to expel the air. Perhaps, too, the lungs may contract by some powers of their own.

The mechanism of respiration, in the saurians and ophidians, is very analogous to that of birds, inasmuch as this function is particularly executed by the motions of the ribs and of the abdominal muscles. In most of the saurians, the ribs are perfectly similar to those of birds, consisting of two portions, united by a moveable articulation, and forming an angle, which is opened in inspiration, and closed in expiration. The muscles which put them in motion are analogous to those employed for the same purpose in birds.

The ribs of serpents, forming simple arcs, composed merely

merely of an offeous portion, are inclined backwards, and brought near the vertebral column in expiration, and are extended in infpiration. Elevators of the ribs, fimilar to thofe of man, but larger in proportion, produce the latter effect, in which they are affifted by intercoftal mufcles. The mufcles carrying the ribs backwards, and thus producing expiration, lie within the cheft. They are fixed to the fides of the vertebral column, and correfpond in number with the ribs. They are narrow and flattened, forming a kind of mufcular ribbons, paffing from the vertebral column, over one rib, to be fixed in the next. Other mufcular ribbons are attached to the infide of the ribs, defcend to be joined together, and then extend acrofs, ending in a thin aponeurofis, which unites the ribbons of each fide. Thefe compofe the abdominal mufcles, and comprefs the vifcera of the great cavity.

Refpiration, which confifts in warm-blooded animals of a conftant regular fucceffion of alternate infpirations and expirations, hardly admitting even a very fhort interruption, is performed in reptiles at irregular and long intervals, admitting of very long fufpenfion, and capable, therefore, in a much greater degree than in the former claffes, of modification by the will of the animal. Hence Linnæus affigned a "pulmo arbitrarius," or voluntary power over the refpiratory function, as a diftinguifhing attribute of the clafs. The difference, however, between the reptiles and warm-blooded animals is in the length of time for which they can do without refpiration: after a longer or fhorter interval, its renewal is equally neceffary to both.

All reptiles continue breathing conftantly as long as they are awake; and the turtles moft frequently of all. It is well known that they cannot remain long under water; but are obliged, at fhort intervals, to come to the furface for a frefh fupply of air. Blumenbach obferved water newts, when placed in a deep veffel of water, fwim up to the top frequently for the purpofe of drawing breath.

"On the whole, however," continues Blumenbach, "reptiles cannot only go much longer without breathing than warm-blooded animals, but they can alfo continue unhurt in vitiated air for a much more confiderable time.

"Tortoifes have been known to live more than a month with their jaws tightly tied, and their noftrils clofed with fealing-wax, (Mery, in Mem. de l'Acad. des Sciences, avant 1699, v. 2.) On the fame point we may mention the puzzling, but fufficiently authenticated inftances, of toads found alive in the middle of folid trunks of trees, and even in maffes of marble and other ftones. (See Luidius in Lithophylac. Britann. p. 112. Le Cat in Allion du Lac, Melanges d'Hiftoire Naturelle, v. 3. p. 95. Gentleman's Magazine, v. 26. 1756, p. 74. Guettard in Mem. fur differ. part. des Sciences et Arts, v. 4. p. 615. Hift. de l'Acad. des Sciences de Berlin, 1782.) There are numerous citations in Haller, de Corp. Hum. Fabrica et Function. v. 7. p. 151, and Kaeftner, in the Preface to the German verfion of the Stockholm Tranfactions, v. 3.

"Reptiles can alfo bear to breathe fixed and phlogifticated air much longer than warm-blooded animals. In my experiments at the celebrated cavern of Pyrmont, I conftantly found that pigeons could hardly be reftored to life if their immerfion in that bath of carbonic acid gas was protracted into the fecond minute. Frogs, however, recovered after ftaying in it five, fix, feven, and even nine minutes. The event of fimilar trials, made in the famous grotto del Cane, near Naples, correfponds to thefe. (See Nollet, in the Mem. de l'Acad. des Sciences de Paris, 1750, p. 72. Murray, in the Swedifh Tranfactions, 1775, v. 36. p. 249.) Della Torre found that a toad lived for half an hour in that grotto, and that a newt was ftill alive, after having been immerfed in this pernicious atmofphere an hour and a quarter.

"Carminati has already fhewn how much fooner confined air proves fatal to warm-blooded animals, than to the amphibia. (De animalium ex mephitibus et noxiis halitibus interitu, p. 96.) When I have enclofed two fparrows under one bell-glafs, and two frogs under another of the fame fize, the former have perifhed in convulfions from the vitiated ftate of their air, while the atmofphere of the other glafs had experienced fo little change, that a candle or burning coals were not extinguifhed by it." Specimen, p. 1.

The experiments of Boyle (Philof. Tranf. 1670, N° 62.), and the Florentine academicians, which have been fince moft frequently repeated, have fhewn that ferpents, frogs, &c. can remain very long (from two or three to ten or twelve hours) under an exhaufted receiver.

The nature of the changes produced in the air by the refpiration of reptiles, has been examined by Spallanzani (Rapports de l'air avec les etres organifés, publies par Senebier, 3 tom. 8vo. Geneve, 1807); Mr. Ellis (Inquiry into the Changes produced on Atmofpheric Air, &c. 1807, and Further Inquiry, &c. 1811,) and others. The latter author prefents us with a fummary of all that has been afcertained, as well as with experiments of his own; we, therefore, extract them in his own words from the works juft quoted.

"To obtain a knowledge of the fpecific changes which the air fuffers by the refpiration of the amphibia, the following experiments were inftituted. A toad, fupported on a fmall hoop, was inclofed in one hundred and eight cubic inches of atmofpheric air contained in a jar inverted over water, and ftanding in a room varying from 55° to 60° Fahrenheit. He died on the fifth day. The water had rifen confiderably in the jar, and the refidual air was ftill farther diminifhed by agitation with lime-water, which it rendered turbid. Fifty parts, after being wafhed in lime-water, were next fhaken in the eudiometer with the liquid fulphuret of potaffa, and loft only one part of its bulk. The experiment was repeated by confining another toad, in the fame manner, in another jar containing forty cubic inches of atmofpheric air, inverted over mercury. Under the hoop which fupported the animal, was placed a fmall cup, containing 1.5 cubic inch of the water of potaffa, which floated on the mercury. The whole was then fet afide in a room, of the temperature of 64°. By the twelfth hour, the mercury had rifen nearly half an inch into the jar, which was thickly moiftened with vapour, and the breathing of the animal feemed rather languid: by the twenty-firft hour, he breathed very faintly; and, by the twenty-fourth hour, he had ceafed to breath. The jar was allowed to ftand fome hours, at the end of which time the mercury ftood about eight-tenths of an inch high, and one-tenth of an inch of fluid was depofited on its furface. The jar was now raifed, and diluted fulphuric acid being poured into the alkaline folution, excited in it a very brifk effervefcence. It is inferred, therefore, from thefe experiments, that the oxygenous portion of the air almoft entirely difappears during the refpiration of thefe animals, after which they ceafe to breathe; and that a large portion of carbonic acid is at the fame period produced.

"Proceeding on the fuppofition, that the lofs in the bulk of air, evinced by the afcent of the mercury, in the laft of the foregoing experiments, arofe from the attraction of the carbonic acid by the alkaline folution, we endeavoured to afcertain the proportion which this lofs of bulk bore to that of the whole air originally employed. With this view a frog was procured, and placed in a jar of the capacity of forty cubic inches. Under the hoop which fupported

ported him, about half way up the jar, was placed a fmall cup, containing one cubic inch of the water of potaffa; and the jar being then filled with atmofpheric air, was inverted into a difh of mercury, and kept fteady by a weight preffing upon it. In the room in which the animal was placed, the barometer ftood at 29.2 inches, and the thermometer at 61°. At the end of twenty-nine hours, the animal was refting quietly on the hoop, with no appearance of diftrefs, and the mercury in the jar, when that in the difh was brought to a level with it, had rifen fix-tenths of an inch. In twenty-four hours more, the frog was ftill alive: his refpiration feemed now to labour, and he rofe often to the top of the jar, as if defirous of efcaping, or of obtaining frefh air: the mercury had now rifen to 1.15 of an inch. From this time, the difficulty of breathing continued to increafe, and, at the clofe of the fifty-ninth hour, from the commencement of the experiment, after having lain quiet for a confiderable time, he gave a convulfive ftruggle, and moved no more. The mercury in the difh was now brought to a level with that in the jar, and its height was 1.2 of an inch. The barometer, at this period, was 29.8, and the thermometer 65°.

"In order to examine the refidual air, we plunged the difh under water, which rifing into the jar, difplaced the mercury, and the cup, with its folution, was then withdrawn under water. The refidual air fuffered no diminution by being fhaken with lime-water, nor by contact with phofphorus, but it loft rather more than $\frac{1}{100}$ by agitation with the liquid fulphuret of potaffa. The jar originally held forty cubic inches, but the animal, with the hoop, cup, and folution, occupied a fhare equal to four, fo that the actual bulk of air employed was 36 cubic inches. Having placed the jar on its bottom, water, to the quantity of 27 cubic inches, was poured in till it reached the point to which the mercury, during the experiment, had rifen; and this, therefore, indicated the volume of refidual air: it then required nine cubic inches more of water to fill the jar completely, which, confequently, was the bulk of air that had difappeared. Hence, therefore, we have $\frac{27 \times 29.8}{29.2} = 27.5547$, but $\frac{4 \times 27.554}{483} = 22819$ and $27.554 - .22819 = 27.32651$, the corrected volume of air at the clofe of the experiment. But farther, $36 - 27.32651 = 8.67349$, and $\frac{8.67349}{36} = \frac{1}{4.15}$, fo that the diminution of bulk which the air fuffered in this experiment is rather greater than $\frac{1}{4.54}$, the proportion of oxygen gas which the atmofphere contains. In a fecond experiment, another frog lived in the fame volume of air about 60 hours, and the diminution which it fuffered, after making the neceffary reductions, amounted to $\frac{1}{4.868}$ of the whole. Where the carbonic acid, formed by the refpiration of another frog, was fuffered to remain, the jar, after the death of the animal, adhered firmly to the faucer in which it was inverted, and, when cautioufly elevated, the furrounding mercury rufhed in; and occupied only about one-tenth of the fpace which it filled in the above-mentioned cafes: the inferences deducible from thefe facts, inftruct us, that the diminution which atmofpheric air fuffers by the refpiration of thefe animals, bears a near proportion to the oxygen gas which it contains, when all the carbonic acid is removed: and as a fmall lofs of bulk likewife takes place when this acid is allowed to remain, we muft afcribe a part of the obferved diminution to the neceffary lofs which always accompanies the converfion of oxygen gas into carbonic acid.

"It follows from the preceding feries of experiments, that the oxygenous portion of the air is changed by the refpiration of amphibious animals in the fame manner as by that of the other claffes, carbonic acid, in proportion thereto, being, in all cafes, produced; and that when the whole, or nearly the whole, of that gas is fo changed, the animal no longer furvives. But, if the animal die when all the oxygen gas is changed, and all the air that has difappeared when the carbonic acid is removed, he oxygen gas, then the bulk of air that remains, and is unchanged, muft confift wholly of nitrogen gas; and as this nitrogen gas, joined with the oxygen gas that has difappeared, makes up the whole bulk of air originally employed, it follows alfo, that, while the oxygen gas of the air has diminifhed and fuffered change, the nitrogenous portion has continued undiminifhed and unaltered.

"During all thefe changes operated on the air contained in water, by the refpiratory functions of aquatic animals, the water itfelf feems to fuffer little or no alteration. Mr. Carlifle took feparate glaffes, each containing one pound of diftilled water, which was previoufly boiled to expel all its air, and then inverting them over mercury, he put into them one gold fifh, one frog, two leeches, and one frefh-water mufcle. The animals were confined feveral days in thefe fituations, and expofed to the fun during January, in temperature 43° and 48° Fahrenheit; but no air-bubbles were produced in the veffels, nor was there any fenfible diminution of the water. The frog died on the third day, the fifh on the fifth, the leeches on the eighth, and the mufcle on the thirteenth day. This experiment was made to afcertain the changes produced in water by the refpiration of aquatic animals; but the water had not undergone any chemical alteration. See Croonian Lecture in the Philof. Tranf. 1805." Inquiry, p. 83—88.

Mr. Ellis adduces fome additional evidence in his Further Inquiry. "The experiments already detailed in the former work clearly prove, that frogs and toads which belong to this clafs, entirely convert, by refpiration, the oxygen gas of the air into nearly an equal bulk of carbonic acid, without producing any change in its nitrogenous portion. Dr. Carradori alfo difcovered, that thefe animals lived much longer when they were immerfed in water that had a free communication with the atmofphere, than when the air was excluded. (Phil. Mag. vol. 16. p. 245). According to Spallanzani, frogs die fooner in boiled, than in common water. In their refpiration, they confume oxygen, and form carbonic acid. Thofe which have been recently fed, confume more of this gas than thofe which have fuffered a long abftinence. Under great cold they become lethargic, but their heart ftill continues to beat, and they ftill, in a fmaller degree, continue to change the air; but the confumption of oxygen increafes with the increafe of temperature. Thefe animals alfo change the air by their fkin, as well as by their lungs; and act upon it after death, and under putrefaction. (Rapports, &c. tom. i. p. 468.) The ova of frogs were likewife found to require air to carry on their evolution. Small tadpoles, while yet attached to the egg, were confined in veffels half filled with water, while the other half contained air, or oxygen or nitrogen gas. Thofe in the two former veffels were perfectly developed, and became large enough to fwim about; but thofe confined with nitrogen perifhed. Rapports, &c. tom. i. p. 466.

"Spallanzani extended his experiments to many other ani-

mals

mals of this clafs, and obtained fimilar refults. Different fpecies of ferpents he found to die in hydrogen gas, or when confined under water, but to live in common air, and convert its oxygenous portion into carbonic acid. They became lethargic from cold, and the heart then beat very flowly, or not at all, the refpiration was then alfo fufpended, and little or no effect was produced in the air. The fkin of thefe animals acted upon the air, as well as the lungs (Rapports, &c. tom. i. p. 249.); and when the blood was reddened by expofure to the air, its oxygen alfo difappeared, and carbonic acid was produced. (Rapports, &c. tom. i. p. 239. 263.) Similar refults were obtained in experiments on the refpiration of vipers, tortoifes, lizards, and falamanders. Rapports, &c. tom. i. p. 275. 287. 295. 353.

"The preceding facts fufficiently fhew, that various animals in all the foregoing claffes, and in every ftage and form of their exiftence, require the prefence of oxygen gas to maintain the functions of life; that this gas, by the exercife of thefe functions, is converted into carbonic acid; and that the degree in which this converfion proceeds, depends much on the healthy condition of the animal, and the vigour of its circulating fyftem. Since, alfo, in every inftance where the experiments have been made with the requifite accuracy, the bulk of carbonic acid produced, nearly or exactly equalled that of the oxygen which difappeared, we may conclude, from analogy, that fuch is univerfally the extent to which this change in the air takes place in animal refpiration; and fince, farther, the nitrogen gas of the air appears to fuffer no neceffary change in the exercife of this function, we may alfo conclude, that as far as regards the air, the fubftitution of an equal bulk of carbonic acid for the oxygen gas that is loft, comprifes the only effential change which the atmofphere experiences during the performance of this animal procefs." P. 269—272.

Vital Temperature.—"Since the refpiratory organs," fays Blumenbach, "may, with great probability, from the numerous inveftigations and difcoveries of the moderns, be regarded as the principal fource of animal temperature, we follow a natural arrangement in paffing from the confideration of their ftructure and functions, to a fhort view of the differences between the natural heat of reptiles and warm-blooded animals.

"Animals, whofe lungs are moft compact, receiving the greateft fupply of blood, and furnifhed with all the apparatus neceffary for fending the whole circulating mafs through the minor circulation, are obliged to keep up the refpiratory procefs uninterruptedly from the time of birth, expelling, inftead of the pure aerial fluid which they infpire, a noxious air, which corrupts the furrounding atmofphere if confined, poffefs a high natural temperature, about the 98th degree of Fahrenheit's fcale in man, rather higher in fome mammalia, and particularly in birds. In reptiles, on the contrary, poffeffing lungs of a rare and loofe texture, with comparatively flender fupply of blood, refpiration is irregular, interrupted, and in fome meafure arbitrary; they very flowly vitiate confined air; and exhibit a temperature exceeding, by a few degrees only, that of the furrounding atmofphere. One or two degrees, I fay, according to the refults of accurate obfervation on tortoifes (Walbaum Chelonograph. p. 26.): for my own experiments on amphibia have not exhibited refults fufficiently conftant to allow me to draw any certain inference from them." (Specimen, &c. p. 18.) Braun, indeed, has afferted, in the Nov. Comment. Acad. Petrop. t. 13. p. 427, that frogs poffefs only the temperature of the furrounding medium; but the facts which we fhall advance prefently, completely difprove this affertion.

The power which modern inveftigations have proved warm-blooded animals, and more particularly the human fubject, to poffefs in fo high a degree, of being able to endure expofure to heat much above the natural temperature of the body, without having their own heat increafed; and, on the contrary, of bearing, with equal facility, the moft intenfe cold, is not withheld from the amphibia, as is proved by the facts which we have related, in order to fhew the tenacity of life in this clafs. It is not, indeed, clear in thefe cafes, as in the experiments, of which man and different mammalia have been the fubjects, that the reptiles, when expofed to a degree of heat greater or lefs than their own, have maintained their own temperature at an uniform ftandard; on the contrary, indeed, it feems that in a great cold their heat is abftracted, and they become frozen; and it will alfo be feen, from facts to be brought forward prefently, that their heat is varioufly changed under different circumftances. Now we know that the temperature of the mammalia is not raifed beyond its natural level by expofure in an atmofpheric medium of 280° Fahr. (fee Tillet in Mém. de l'Acad. des Sciences, 1764); and that its ftandard is equally undifturbed, when the atmofphere is below the freezing point of mercury. (See HEAT, *Animal*, and MAN.) We may therefore fafely affert that man and the mammalia very far exceed reptiles in the power of refifting either great heat or cold; that is, of maintaining a ftandard temperature under the action of a furrounding atmofphere, confiderably exceeding or falling fhort of their own temperature. The following fummary of facts, concerning the temperature of reptiles, is taken from Mr. Ellis's Inquiry.

"Amphibious animals exhibit a great variety in the ftructure of the refpiratory organs, and, confequently, in the degrees of animal heat. Frogs and land tortoifes poffefs a temperature about five degrees higher than that of the medium they inhabit, according to Dr. Martine. The fame may be faid of fea tortoifes, toads, vipers, and all the ferpent kind, all of whom have lungs of the fame fabric and the fame cold conftitution of body. (Effay on Thermometers, p. 142.) Mr. Hunter obferved that the frog and toad were about four or five degrees warmer than the atmofphere when it was at 35° or 36°; and that, fome hours after death, they gradually fell down to the temperature of the furrounding air. (Treatife on the Blood, p. 298.) The difference of temperature appears to increafe in a warmer atmofphere; for Mr. Carlifle kept three frogs for many days in an equable atmofphere of 54°, and their ftomachs preferved a temperature of 62°. (Philof. Tranfact. 1805, pt. 1.) In an atmofphere of 58°, Mr. Hunter found the thermometer, introduced into the ftomach of a healthy viper, to ftand at 68°; but, after the animal was put into a pan, and the pan into a cold mixture of 10°, where it remained about ten minutes, the heat was reduced to 37°, and, in twenty minutes more, to 31°, nor did it fink lower; its tail now began to freeze, and the animal was very weak. A frog alfo, whofe temperature was 44°, when put into a cold mixture, foon fell down to 31°; and beyond this point it was not poffible to leffen the heat without deftroying the animal. (Obf. on the Animal Economy, p. 104.) A toad being placed in cold water, juft deep enough not to cover his mouth, the whole was put into a cold mixture between 10° and 15°. The water froze around the toad, and, as it were, clofed him in, but he did not die, and therefore was not frozen. Why the animals, mentioned in thefe experiments, died before they were frozen, while thofe which are expofed

expofed to the atmofphere, in very cold climates, do not die, is a point which Mr. Hunter does not pretend to determine; not knowing the difference, he fays, between the effects of a natural and artificial cold. Ibid. p. 89, 90.

"The experiments of Mr. Hunter farther prove that the temperature of moft of the foregoing animals not only falls rapidly in a colder medium, but that it rifes more quickly in a warmer one than that of thofe which poffefs a higher ftandard temperature. In the ftomach of a frog, the thermometer rofe from 45° to 49°; the animal was then placed in an atmofphere made warm by heated water, where it remained for 20 minutes, and upon introducing the thermometer again into the ftomach, the mercury rofe to 64°. (Ibid. p. 90.) A healthy viper was put into an atmofphere of 108°, and, in feven minutes, the heat of the animal, both in the ftomach and anus, was found to be 92°.5, beyond which it could not be raifed in the above heat. An eel, very weak, whofe heat was 44°, which was nearly that of the atmofphere, was put into water heated to 65°, for fifteen minutes; and, upon examination, it was of the fame degree of heat with the water. The heat of a tench was, in ten minutes, raifed from 41° to 55°, both in the ftomach and rectum, by being put into water at 65°.

"He found alfo, that a living and dead tench, and a living and dead eel, put together into warm water, received heat equally faft; and when they were expofed to cold, both the living and the dead admitted the cold likewife with equal quicknefs. (Ibid. 104, 105.) Hence, therefore, the animal heat, in all the claffes of animals hitherto mentioned, whether they inhabit the air or the water, feems to follow nearly that of the medium in which they are placed; and their ftandard temperature cannot, in confequence, be reftricted to any fixed point, but muft be confidered always in relation to that of their furrounding medium.

"Notwithftanding, however, the low degree of heat which thefe feveral claffes of animals poffefs, hardly, in fome inftances, exceeding that of the medium in which they live, yet this fmall excefs is a proof that they poffefs, within themfelves, a power of producing heat. The lofs of heat which infects fuffer under cold, the fall of temperature which many of the vermes clafs undergo from the fame caufe, the melting of fnow by the heat of fifhes, and the decline of animal heat which the amphibia, when expofed to great cold, experience, all demonftrate that the furrounding medium, whether it be air or water, is conftantly drawing off their heat, which renders neceffary as conftant a re-production of it." P. 218—221.

The great fize and beautiful ftructure of the lungs of reptiles lead us to conclude that they are very important organs in the economy of thefe animals, although their ufes and relations are not yet all fatisfactorily afcertained. It feems tolerably certain, that befides their office as refpiratory organs, they render the body lighter for fwimming in many inftances: in this point of view they may be compared to the fwimming bladder of fifh. It is by the inflation of its large lungs, that the cameleon can diftend its body fo remarkably.

"The lungs, too," fays Blumenbach, "are fubfervient in many reptiles to the production of found; — I fay in many, becaufe fome fpecies, even of our reptiles, are, fo far as I know, completely dumb: *viz.* the falamander, lacerta agilis (green lizard), and anguis fragilis (blind-worm); and others utter found very rarely, and only when in great danger, as the water newts; refembling, in that refpect, the mole and hare, which do not cry out until great violence is offered them.

"It has been reported that fome mammalia lofe their voice in particular fituations, as dogs in certain parts of America: the fame thing has been reported of reptiles, for example frogs, which G. F. Müller found to be dumb in many regions of Afiatic Ruffia. Sammlung Ruffifcher Gefchichten, vii. p. 123." Blumenbach, Specimen, &c. p. 15.

Organs of Voice.—The larynx, varying in different genera, as in the other claffes, has thefe characters in common; *viz.* that it has no epiglottis, and is compofed of pieces analogous to thofe of the upper larynx of birds. This is the only vocal organ; there is never an inferior larynx, as in birds. The voice cannot be modified by lips or velum palati, fince they do not exift. The degree of aperture of the mouth, and the motions of the tongue, are alone capable of modifying the action of the larynx.

The cartilaginous fkeleton of the crocodile's larynx contains five pieces: a nearly fquare plate, compofing all the under furface of the cavity. Two circular pieces or handles, fixed near together at one end, in the middle of the front edge of the plate, and at the other, in the middle of the fide. Their body is a little evelated above the fquare plate, and leaves on each fide, between it and that plate, a membranous hollow. The anterior extremity of each piece forms a lateral and vertical prominence, conftituting a kind of pillar under the glottis. To the pofterior external angle of this plate, a branch is fixed on each fide; thefe join together above, and form, with the back edge of the plate, a complete ring, which is the beginning of the trachea.

The glottis is merely membranous, extending from the junction of the two laft-mentioned branches to the middle of the os hyoides, where the membranes compofing it are attached. There are neither ventricles nor chordæ vocales. Two mufcles act on this apparatus. One comes from below the great plate, furrounds the larynx, afcending obliquely backwards, and joins the correfponding mufcle of the other fide behind the glottis, which it has the power of clofing. The other comes from below the back edge of the fame plate; decuffates the former, afcending obliquely forwards, and is fixed to the edge of the glottis, which it opens. The firft half of the glottis correfponds then to the broad and flat cavity of the larynx; the fecond, beginning from the two pillars in front, is merely a long and narrow flit. It is only in ftriking againft the two pillars, that the air can produce a whiftling noife, if indeed any fuch be produced at all.

The glottis of the crocodile of the Orinoco, fays Humboldt, is furrounded by a thick flefhy ring with circular fibres, which the animal can contract to fuch a degree, that the flit or opening of the trachea cannot be diftinguifhed. The glottis refts on a round and flat cartilage, analogous to the thyroid of mammalia. The upper part of the trachea prefents a fingular ftructure, which we mention here, becaufe it feems fubfervient to the production of found. The firft nine cartilages are not complete rings, but are joined together above by a tranfparent, very fine and tenfe membrane. (See Humboldt Recueil d'Obfervations de Zoologie et d'Anatomie comparée, t. 1. pag. 11. pl. 4.) Geoffroy obferved ten annuli thus united in the Nilotic crocodile; Duverney fixteen, in a crocodile diffected at the Academy of Sciences, and the Jefuit Miffionaries in Siam a larger number. To this membrane, ftretched like the parchment of a drum, and thrown into vibrations by the air, the deep and terrific howlings or bellowings of thefe dangerous reptiles are afcribed; the glottis being at the fame time clofed by its mufcular ring. Annales du Mufeum, t. 2. p. 46.

In the iguana, the pillars are fcarcely more prominent within than the reft of the parietes; the glottis is very fhort, ſhort, and the inferior plate goes forwards and becomes broader, being turned up to form the rudiment of an epiglottis.

The ſame ſimplicity of ſtructure prevails in the tupinambis, the common lizard, the tortoiſes, and ſerpents; an inferior plate, and two lateral pieces narrowing a little the edges of the glottis. Theſe animals can only be capable of producing hiſſing ſounds.

The mud tortoiſe has, at the bottom of its organ, a rounded depreſſion, which is not ſo well marked in the turtle; but it has not any vocal chords. In a great land tortoiſe of Madagaſcar, there is a triangular membranous criſta, attached to the lower part of the larynx, and aſcending in the glottis, which it divides into two. This is analogous to a ſtructure very common in the upper larynx of birds. The edges of the glottis are flat, ſharp on the outſide, and touch completely.

In the ſcink, the edge of the glottis is turned a little inwards to form a tenſe membrane, directed backwards.

In the cameleon there are pillars, nearly as in the crocodile, but they are each furniſhed with a tenſe membrane directed backwards, and very fit for vibration. In front of them, on each ſide, a fleſhy protuberance is obſerved, contracting the glottis, which is very ſhort, and terminating in front by a tranſverſe ſlit. But the moſt remarkable circumſtance about the larynx of the cameleon, is a ſmall membranous ſac opening below, between the inferior plate of the larynx, and the firſt ring of the trachea.

Neither the iguanas nor the dragons poſſeſs a ſimilar ſac, although we obſerve in them goitres on the outſide: theſe prominences have no relation to the vocal organs.

The frogs, which are ſo noiſy, have a larynx ſuitable to this character in the ſize and prominence of its vocal chords. The inferior plate of the larynx is a ſlender tranſverſe branch, bearing on each ſide a large ring, which is the origin of the bronchus; for, in theſe animals there is no tracheal tube. On the front of the tranſverſe branch, two oval pieces are articulated, convex externally, and concave internally, ſo as to reſemble kettle-drums. On the lower edge of each a membrane is ſtretched internally, which oppoſes at right angles the courſe of the air. The edge of this membrane forms the chorda vocalis, which is conſequently more iſolated than the cartilages, and freer than in any other animal. Above it is the opening of the ventricle of the glottis, occupying all the concavity of the kettledrum cartilage. The upper edge of this cartilage forms the margin of the glottis properly ſo called. Vicq' d'Azyr conceived that the ventricles communicate by their bottom with the bronchi, and thus aſcribed three openings to the larynx of frogs: but this is a miſtake.

Beſides this apparatus, which is extremely ſonorous, male frogs have two bags, each of which opens by a ſmall hole, not in the larynx, but in the bottom of the mouth, at its ſides. They paſs under the arch of the lower jaw, to make a prominence under the ſkin on each ſide under the ear. Theſe bags are diſtended when the frogs are croaking. They are covered by a muſcular tiſſue capable of compreſſing them. The female frogs, and toads of both ſexes, and the tree-frogs, are deſtitute of the bags; but the latter have a ſimple ſac under the throat. In this larynx there is a muſcle on each ſide to ſeparate the oval cartilages; and a tranſverſe one in front, paſſing between them, and calculated to approximate them. For repreſentations of theſe laryngeal ſacs in the frog, ſee the German collection of Camper's ſmaller writings, vol. 1. pt. 1. pag. 144. tab. 3. fig. 1—4. Vicq d'Azyr has repreſented the rima glottidis of the tortoiſe, frog, and ſerpents, in the Memoires de l'Acad. des Sciences. 1779, tab. 13; and Tyſon that of the rattleſnake, in the Philoſ. Tranſ. vol. 13. The chordæ vocales, too, are larger in the male than in the female frog.

Voice of Reptiles.—The tortoiſes and turtles are ſaid to have the power of producing a more or leſs ſtrong hiſſing, when affected by any lively feeling; but we do not know of any very clear and ſatisfactory teſtimony on the ſubject. Pliny's obſervation about the ſnoring of turtles when floating aſleep on the water, has not been confirmed. The large iguanas utter ſharp whiſtling or hiſſing ſounds as they run about the tops of trees. Several ſerpents hiſs, and the large ſpecies very loudly. The noiſe made by the tail of the rattleſnake is not a vocal ſound, but produced by a peculiar organ, which we ſhall deſcribe.

Daudin aſſerts, that ſalamanders produce two kinds of feeble ſound out of the water; the firſt is a low ſound, produced in the throat, which they ſwell for that purpoſe; the ſecond conſiſts in a ſlight ſtriking of the two lips together, without any motion of the throat.

According to the traveller Bartram, crocodiles produce moſt prodigious noiſes. The ſound is terrific, particularly in the ſpring, when theſe dangerous animals copulate. The noiſe reſembles diſtant thunder, ſhaking the country and making it re-echo far and wide. When they are thus bellowing by hundreds and thouſands at a time, we might ſuppoſe, ſays Bartram, that ſome violent ſhock agitates the globe, and ſhakes it to its very foundations. He alſo ſtates, that when they ſtrike their jaws together they make a ſurpriſing noiſe, like that of a heavy plank forcibly beaten againſt the ground.

Humboldt ſays that the young crocodiles make a noiſe like cats; and that they utter very piercing cries, juſt after eſcaping from the egg, if attacked by a dog. He never heard any vocal ſound produced by the old crocodiles; although he lived among them five years, and the fire often attracted them within a few paces of the tents at night. The Indians aſſerted that the crocodile makes a noiſe like that of a cow; that its voice is very terrific, but ſeldom heard, and ſometimes juſt before an earthquake, the approach of which they are ſaid to diſcern. Recueil d'Obſ. de Zool. et d'Anat. Comp. p. 11.

Organs of the Generative Functions.—There is a very cloſe analogy in the ſtructure of theſe parts between reptiles and birds: in both claſſes there is a cloaca, that is, a cavity common to the generative organs, the feces, and the urine; in both the male has teſticles incloſed in the abdomen, while the female organs conſiſt of ovaries and oviducts. The young being leaves the mother in the form of a ſmall egg, which is generally developed out of the body. The generative proceſs, however, in many inſtances, exhibits in this claſs very ſtriking peculiarities.

Male Organs.—The teſticles: the ſituation and ſtructure of theſe glands in the three firſt orders are very analogous to thoſe which they have in birds. They are conſtantly found in the abdominal cavity, united to the inferior ſurface of the kidnies (in the chelonians), in front of the latter viſcera on each ſide of the vertebral column (in the ſaurians and ophidians), or immediately under their anterior portion (in the batracians). Their form varies in the different genera; they are ſeparated, in the ſalamanders, into two ſpherical bodies, placed one before the other.

The kidney, teſtis, and epididymis, lie cloſe together in the teſtudines, according to Blumenbach; but each of the three organs may be diſtinguiſhed by its peculiar colour and ſtructure on the firſt view. There is much obſcurity in the different deſcriptions of the male organs in the turtle and tortoiſe. Schneider has collected the various obſervations on this ſubject in his natural hiſtory of the genus teſtudo.

Their ſubſtance exhibits, in the tortoiſes, large faſciculi, of which the diviſions paſs in various directions, united by cellular tiſſue: theſe faſciculi are fine, cylindrical, and eaſily ſeparable in the lizards. In the crocodile, according to Geoffroy, the teſtes are like thoſe of fiſh, narrow and elongated, and lying above and in front of the kidnies (probably more correctly in front of and below theſe glands). In the batracians we can diſtinguiſh merely an agglomeration of ſmall white grains interſperſed with blood-veſſels. No corpus Highmori can be diſcerned.

Yellow appendages, conſiſting of a fatty ſubſtance ſurrounded by a membrane, and floating in the abdomen, are connected to the front end of the teſtes in the frogs and toads.

The *epididymis* of the chelonians is a packet made up by the convolutions of a large canal (the vas deferens), which is tortuous in its whole courſe, and ends in the cloaca at the part correſponding to the baſis of the penis and its canal. It forms, in the lizards, a detached body, large and pyramidal, larger than the teſticle, adhering to it only by a ſmall thread, and evidently made up entirely of the convolutions of the vas deferens. The latter paſſes along the outer edge of the kidney to the cloaca, in which it opens.

In the crocodile the ſemen is conveyed into two veſiculæ of conſiderable ſize, contiguous to each other, placed at the back of the common cloaca, and partly included in a cartilaginous ſac. They open into the cloaca by ſix or ſeven holes on each ſide, arranged in a circular form round the meatus urinarius. Geoffroy. If theſe are veſiculæ ſeminales, it is the only example we know among reptiles of ſuch organs.

The teſtis is long and ſlender, and the relative bulk of the epididymis is leſs in the ophidians; it ſoon changes into a vas deferens, alſo very tortuous, opening in this, as in the preceding orders, into the cloaca. In the latter only the canals are inſerted in a papilla, which has been incorrectly deſcribed as a penis. A more minute account of theſe organs in the viper, may be ſeen in Charas, Deſcription Anatomique de la Vipère.

Veſiculæ Seminales.—There is no reſervoir analogous to the veſiculæ ſeminales properly ſo called, nor to the acceſſory veſiculæ of ſome mammalia in any of the other claſſes of vertebral animals. They have been ſpoken of in the viper and the batracians, as well as in ſome birds; but it ſeems that a ſimple dilatation of the vas deferens has been miſtaken for them. Poſſibly future reſearches may ſhew that the arrangement mentioned above in the crocodile conſtitutes an exception to this remark. This is the ſtatement of Cuvier. Blumenbach ſpeaks of large veſiculæ ſeminales in the frog, which are wanting in the toad. § 324. (See Roeſel Hiſtor. Ran. Noſtr. tab. 5, 6, and 21.) Charas, in his deſcription of the viper, ſpeaks of two reſervoirs connected with the vaſa deferentia, and always full of a fluid, like that of the teſticles, under the name of veſiculæ ſeminales.

The ſecretion of the teſticles, as obſerved by Spallanzani in the frog and toad, was a tranſparent fluid like water. From the parts, which he calls veſiculæ ſeminales, of the frog, he could procure at the time of copulation from two to three grains of this fluid. In the water newt it was, in colour and conſiſtence, like thick milk. He could not diſcover in it any remarkable ſenſible property—nothing pungent—nothing acid or alkaline. (Diſſertations, v. 2.) He alſo found the ſeminal fluid, both of the frog and newt, to abound with the living vermiculi. Tracts, v. 1. p. 300 and 301.

Organs of Copulation.—There are two ſpecies of union between the male and female. In the greater number there is a male organ introduced into the body of the female, and conveying the fecundating liquor: but in the batracians, which have no male organ, there is merely a conjunction of their bodies, it is a prehenſion by the male rather than a true copulation.

In the males of thoſe batracians which copulate thus, there is a peculiar organiſation of the ſkin of the hand. Firm tubercles, compoſed of hard, blackiſh or brown papillæ, cover not only the thumb, but alſo the palm of the hand. Theſe being preſſed into the ſkin of the female, give the male a very firm hold. They diſappear after the ſeaſon of copulation, and are not ſeen again until that ſeaſon recurs. The copulation of the frog kind is effected in the following way: the male aſcends the back of the female, paſſes his front limbs under her axillæ, and carries them round the cheſt, until the fingers croſs in front. He continues graſping her firmly in this way until the laying is finiſhed. The poſterior part of his body paſſes beyond that of the female, ſo that he can fecundate the eggs as they are expelled, and he is ſaid to aſſiſt in that operation. They remain joined for ſeveral days, and the graſp of the male is ſo firm, that great force is neceſſary to ſeparate him. Contuſion and laceration of the breaſt, and even the death of the female, ſometimes follow the violent ſtraining of the male. (See Spallanzani's Diſſertations, vol. i. p. 17.) The males are more brilliant at the ſeaſon of copulation, which takes place only once a-year, in the early ſpring; they inflate their vocal bladder more frequently, and indulge in their croaking noiſe. In the ſalamanders a creſt, with divided edge, appears on the back and tail, and is afterwards, in great meaſure, loſt.

The duration of copulation in the frogs is inverſely proportional to the warmth of the atmoſphere. When this is conſiderable, the female will be free in five or ſix days; but, in a cold ſeaſon, the embraces of the male continue for eight or nine days. The ſeaſon of re-production is the beginning of ſpring: in the very firſt days, the frogs begin to ſtir themſelves in our marſhes and ponds: they copulate, lay and fecundate their eggs very ſoon. At the ſame ſeaſon, the tortoiſes, lizards, and ſerpents, accompliſh the ſame proceſs. Sometimes frogs are found united even before the froſts have ended. Daudin found two frogs in copulation in the middle of February, the thermometer of Reaumur at 3° above zero; it deſcended in the night to 4° below 0; and the pond was frozen for two days; at the end of which time the female began to lay. Hiſt. Nat. des Reptiles, vol. i. p. 207, 208.

One of the toads, on which Spallanzani made his experiments, copulates in the beginning of March or end of February, before all the ſnow is melted; the proceſs laſts ten, twelve, fourteen, or even twenty days, if the ſeaſon be cold. Spallanzani, ch. 3.

The abdomen ſwells greatly in both ſexes during copulation; in the female, from the enlargement of the ova; in the male, from the depoſition under the ſkin of a very limpid water, which diſappears after the laying.

The tree-frogs, at leaſt that of Europe (hyla viridis) do not copulate like the frog and toad. The male fixes himſelf on the female, by merely applying his anterior paws under her axillæ, and employing the tubercles of the fingers. He remains in this ſituation for twelve or fifteen hours, or even, according to Roeſel, three days.

The ſalamanders do not copulate at all; the male places his head on that of the female, and diſcharges the ſeminal fluid, which is received by the female organs. See Spallanzani,

zani, Diff. vol. 2; and Latreille, Hiftoire Naturelle des Salamandres de France.

Penis.—The chelonians have one; moft of the faurians, and the ophidians, have two; and the batracians none. There is a papilla in the cloaca, in place of the penis, but none in the toad.

The relative fize of the organ is more confiderable in the chelonians than in the mammalia and birds. It is long, nearly cylindrical, and expanded at the end, which terminates in an obtufe hook-like point, fomewhat refembling the end of the elephant's trunk. A deep groove runs along the whole upper furface of the member, and is even deeper near the glans. It terminates on the broad expanded end of the latter, by an orifice divided into two by a papilla. The approximation of its edges converts this groove into a canal: it fupplies the place of the urethra. This penis is compofed of two corpora cavernofa, confounded together in a part of its extent. They begin by two vafcular fwellings analogous to the bulb of the urethra: their tiffue is continued into two canals, of which the fibrous parietes, at firft thin, foon become very thick, while their cavities diminifh, and are united near the glans into one. The whole large fwelling compofing the glans is merely a developement of the vafcular tiffue of the latter, covered by a loofe and plaited fkin, and fupported by a prolongation of the fibrous fide of the corpus cavernofum.

The fkin of the groove is covered by a cavernous texture, analogous to that of the oftrich; and there is, on each fide of this groove, a canal, the orifice of which is in the cavity of the peritoneum, on each fide of the bladder, while the canal itfelf is prolonged in the fubftance of the penis, as far as the glans, where it ends in a cul-de-fac, without its fides appearing perforated in any part.

This penis has two retractor mufcles, arifing in the pelvis, and reaching as far as the glans. They fold back the penis in the cloaca, fo that, like the penis of the oftrich, it fhuts the orifice of the rectum, and that of the bladder. Erection, and the action of the fphincter, bring it out of the cavity.

The penifes of the lizards and ferpents are fhort, cylindrical, commonly befet with white, hard, and pointed papillæ, which have been tolerably well compared to the prickles of the hedge-hog. Thefe organs, in their collapfed ftate, are drawn within the fkin of the tail: when erect they are protruded, and appear at each angle of the external flit of the cloaca. They have two retractor mufcles, arifing under the firft caudal vertebræ. Tyfon has figured the penis of the rattlefnake and viper in the Philof. Tranf. v. 13, tab. 1; and the latter is minutely defcribed by Charas.

The penis of the crocodile is fingle, and lodged in a fold of the anterior part of the cloaca. It is compofed of a firm cartilaginous fubftance, terminated by a glans of fofter texture. It is excavated in its whole length by a deep groove. It has a very large retractor mufcle, which is fo confiderable as even to caufe a fwelling of the tail.

In the faurian reptiles, as in the frog and falamanders, the male fixes himfelf on the female, and obliges her to turn towards him the pofterior part of her body, and a real copulation enfues.

The act is differently accomplifhed in the ferpents: the male and female twine round each other, are clofely connected by feveral turns, and remain thus adherent for one or two hours. Is the fmall horny fpur, fituated on each fide of the anus in the boæ, and retractile under the fkin, employed at all by the ferpent as an organ of prehenfion, like the cutaneous tubercles of the hand of the ranæ? The faurians and ferpents conceal themfelves carefully for this purpofe.

Although the chelonian reptiles feem fo little calculated for copulation, this procefs takes place in them, the male fixing himfelf to the female by attaching the nails of his front limbs to the foft fkin of her neck. Naturalifts are ftill uncertain, whether turtles are joined plaftron to plaftron, as Lacépède has afferted in his Natural Hiftory of Oviparous Quadrupeds, or whether the male mounts on the back of the female, as Bomare has reprefented it in his Dictionnaire d'Hiftoire Naturelle. From the word *cavalage*, employed by the French mariners to denote this union, we may infer that they copulate like the frogs: the expreffion denotes clearly that the male is mounted on the female as the ftallion is on the mare (cavale). Catefby, in his Natural Hiftory of Carolina, afferts that they remain united for many days.

Female Organs of Generation.—Reptiles have two ovaries, ufually much more confiderable than the fingle ovary of birds. For moft of the year thefe bodies are fmall: but they acquire, at the propagating feafon, an extraordinary development, and thus diftend the abdomen very remarkably. This is particularly obfervable in the frog kind.

In autumn and winter, fays Spallanzani, the immature eggs lie all in the ovarium, which is divided into two lobes: thefe lobes confift of leffer lobes, each of which is invefted with a peculiar membrane. The eggs are of two fizes; fome very fmall, fo as to be fcarcely vifible with the naked eye; others feven or eight times larger; both kinds are globular. The fmaller are of a livid grey colour: of the larger one hemifphere is white, the other black. The flighteft touch is fufficient to burft them, after which they are refolved into a cineritious vifcid liquor. (Differtations, v. 1. § 4.) The black fpots of the furface, fuppofed by Valifneri and others to be the rudiments of the tadpole, are attached to the internal membrane, and have no connection with the eggs. In the fpring the eggs of the largeft kind are ftill larger, and they are mature when copulation takes place. In the firft periods of copulation, they are found in the fac of the ovarium; during the fucceeding times, partly in the ovarium and partly in the oviducts, where they become enveloped by their covering of vifcid tranfparent mucilage.

The ovaria of the falamander contain a multitude of little eggs of a yellowifh-white colour, fmaller than hufked millet, and not floating loofe in the cavity of the ovaria, but adhering to their fides. Thefe increafe in fize at the approach of fpring.

The ovaria are connected to two long productions of peritoneum, which are fixed on each fide of the fpine down to the pelvis. The ova are ranged along the loofe edge of this fold, either in a fingle row, as in the chelonians, or agglomerated in a much larger number, as in the batracians. Their blood-veffels extend between the laminæ of thefe membranous productions. In the batracians there are yellow fatty appendages to the ovaries, like thofe of the tefticles.

In the ferpents, like all their other vifcera, they partake of the elongated figure of the body. The ova, confifting of yellow veficles, refemble rows of beads.

Oviducts.—There are two in all reptiles, like their ovaries. They are membranous canals, fixed on each fide of the vertebral column by a production of peritoneum. They commence by an expanded orifice (fimbriated opening of the Fallopian tube in mammalia), at which the ova enter. The tube is firft conical, diminifhing a little in fize; then it is cylindrical in the reft of its courfe, which has a much greater propor-

tional

tional length than in birds. In confequence of this length of the canal it is plaited on the production of the peritoneum in the chelonian, faurian, and ophidian orders, or extremely finnous and folded on itfelf in the batracians. When the curvatures are deftroyed, and the duct is ftretched in a ftraight line, it is four times the length of the animal in the falamander. Its parietes confift at firft of a thin membrane, they become afterwards thicker, and affume the appearance of a glandular ftructure. The oviducts end in the frogs by a dilatation, which opens into the cloaca.

The thick flefhy part of the oviduct in the tortoifes has been frequently called the uterus: the two oviducts open feparately. Caldefi offervaz. intorno alle Tartarughe, tab. 6, fig. 9, 10.

An uterus is alfo fpoken of by fome in the frogs, although the generation of thefe animals has nothing in it like utero-geftation, and the ova are fimply tranfmitted through the tubes, without being retained in them to undergo any part of their developement. "The frogs of this country," fays Blumenbach, "have a large uterus divided by an internal partition into two cavities, from which two long convoluted oviducts arife, and terminate by open orifices at the fides of the heart. As the ovaria lie under the liver, it is difficult to underftand how the ova get into the above-mentioned openings. The uterus opens into the cloaca." (Comparative Anatomy, tranflated by Lawrence, p. 446.) "The toads have not the large uterus, but their oviducts terminate by a common tube in the cloaca." (Ibid.) For delineations of thefe parts in the frog and toad, fee Roefel, tab. 6, 7, 8, and 21. The rana pipa (Surinam toad) has the fame ftructure. See Camper in the 9th vol. of Commentat. Soc. Reg. Scient. Gotting. p. 129. Alfo in his Kleinere Schriften, v. 1. pt. 1. tab. 3. fig. 1.

Female Organs of Copulation.—The male penis in copulation paffes into the female cloaca. Does it go into the oviducts?

The chelonian reptiles have a clitoris very analogous to the penis of the male, from which it differs only in its fmaller fize. It is long, grooved lengthwife, and terminated by a rounded glans. Retractor mufcles, analogous to thofe of the penis, draw back the clitoris into the cloaca, when it has been extended.

No clitoris has been difcovered in the other reptiles.

Dorfal Cells of the Rana Pipa (Surinam toad, bufo dorfiger).—It is fingular enough to meet with in a toad a ftructure analogous to that of the abdominal pouch of the marfupial mammalia. The fkin of the bulk is excavated in the female pipa by a large number of cells, (of which, Cuvier fays, eighty have been counted,) in which the ova are placed, and changed into tadpoles, and the latter grow and are metamorphofed. As far as an examination of individuals, preferved for a long time in fpirits of wine, will enable us to judge, the parietes of thefe cells do not feem to have any thing in their organization diftinct from the reft of the fkin.

Naturalifts fuppofed at firft, that the ova grew on the back of the female, and that the male fecundated them in that fituation: but obfervation of the living animal, and anatomical inveftigations, have fhewn the incorrectnefs of this notion; have proved, that the generative organs refemble thofe of other female toads; that the pipa lays her ova like the other toads; and that the male faftened on her, as in the ordinary mode belonging to this order, covers her with the eggs after they have been fecundated. The eggs are then enveloped in a fluid, which caufes the fkin of the back to fwell round them: thus they are contained in rounded cavities. The tadpoles are produced there, with their membranous tails, and are developed in this fituation, which they do not quit until they have reached their perfect ftate. The female then caufes the cells to difappear from her back, by rubbing it againft hard fubftances. Befides the works of Camper already referred to, concerning the anatomy of this extraordinary creature, fee Blumenbach's Abbildungen, N° 36, for excellent figures of the animal, and of its young in three ftates: 1ft, as a long-tailed tadpole, with fmall proceffes of hind legs, and no trace of fore limbs; 2dly, as a four-footed creature, with the tail reduced to an infignificant fize; and 3dly, with the tail entirely removed. The fkeleton is figured by Schneider, in his Hift. Amphib. Fafcic. 1.

Phyfiology of the Generative Organs.—In the whole clafs it is quite obvious, that the germ or rudiment of the new being is produced by the female in the ovarium, a point which does not admit of direct proof in the mammalia. This "pre-exiftence of the germ" to the act of copulation, and its formation in a peculiar organ of the female, demonftrated fo clearly in reptiles, illuftrate one of the moft curious points in the theory of the natural reproduction of organized beings, or generation, and overturn many of the fpeculations on that fubject. Thefe germs acquire confiderable fize in the ovaries, and are therefore diftinctly vifible before the approach of the male. They pafs from the parts juft mentioned into the oviducts, and thence out of the body through the cloaca, having received in their paffage through the ducts fome external coverings. An application of the fecundating liquor fecreted by the male is neceffary to the evolution of thefe germs; they may be ejected from the body without the embraces of the male, as in the frog, toad, or newt, if they are forcibly feparated from the male after copulation has begun, but then they are not evolved.

Swammerdam and Roefel were of opinion, that the eggs were loofe in the abdominal cavity, and taken up thence by the oviduct. Spallanzani found them in the abdomen only thrice in more than two thoufand diffections; and hence fuppofes that the circumftance muft have been a deviation from the accuftomed courfe in thefe inftances.

Although the motions and vital functions of reptiles feem very languid in comparifon to thofe of the warm-blooded claffes, they exhibit confiderable ardour and manifeftations of lively feeling in their amours. "As foon," fays Spallanzani, "as the eggs begin to be difcharged, the agitation of the female is extreme; fhe darts backwards and forwards, rifes towards the furface of the water, and then finks, keeping the hind legs conftantly ftretched out, and croaking in a low voice. The male, keeping his hind legs clofe to his body, throws himfelf into ftrange contortions, and accompanies the croaking of the female with a kind of interrupted noife, which I cannot exprefs by words." Differtations, v. 2. § 11.

In the work juft quoted, which contains the moft original and interefting collection of facts concerning the whole affair of generation, Spallanzani gives the following account of the amours of the water newt, which are the more curious, inafmuch as there is not only no real copulation by the introduction of a male member into the female organs, but not even any conjunction of the bodies, as in frogs and toads. "The male purfues the female, which at firft makes a fhow of flying, but then ftops of her own accord. He then approaches her in fuch a manner, that the lower part of his head comes in contact with the upper part of the head of the female; and this is done while the animals are in fuch a pofture, that their bodies form an angle,

angle, of which the point is made by the union of the two heads; or they may only join muzzle to muzzle. The bodies are always very near together, fo that the angle formed by the two heads or muzzles is always very acute. Then the male erects that dentated prominence, which is placed on his back, and agitates it in a curious manner: he alfo moves his tail brifkly, bending it about, and ftriking very gently the fides of the female. During this time he emits from the aperture of the anus, now unufually tumid and dilated, a copious jet of femen, which mixes with the water, and thus diluted arrives at the anus of the female, alfo more enlarged than ufual. In this important operation, then, the anus of the male is never in contact with that of the female, which maintains a greater or fmaller diftance, and never fhews any part characteriftic of her fex. After the male has difcharged this jet of femen, he refts for a while, on fome occafions quitting the female; he then returns to his employment, and repeats the contortions of his tail, and the emiffion of femen." § 80.

In the land newts there is a momentary copulation: "in the cleareft days, and in the places moft expofed to the fun, the male runs after the female, and when he has overtaken her, he twines himfelf about her, and unites his genitals to her's, but this union may be termed momentary, after which they part." § 81.

The vehemence of the propenfity in amphibia is fo remarkable, that they actually will copulate with other fpecies, as frogs with toads, &c. No example of hybrid offfpring, from fuch a conjunction, has been recorded. It has alfo been known, that frogs, in want of a female, have copulated with other males, or with dead females.

That the animals are entirely abforbed by the powerful emotions accompanying this act is evinced by a feries of difgufting experiments of Spallanzani, purfued and multiplied with an unrelenting and unneceffary cruelty, and related quite coolly, without evidence of remorfe or the flighteft apology. He pricked, cut, and hacked the male frog and toads, without making them loofe their hold; amputation of the limbs, and of the head, was equally ineffectual.

Males, after fuffering amputation of the fore or hind limbs, renewed their fituation, and completed the generative act. "Nay, even the decapitation of a frog did not ftop the embraces or fecundation. It is well known, that thefe animals are fo tenacious of life, that that operation does not take it away immediately. That of which I am fpeaking was thrown into convulfions; but neither the fore-feet nor legs quitted the breaft of the female, which brought forth her fetufes in an hour and three quarters, and I was an eye-witnefs to the male's befprinkling them with femen; that they were fecundated there can be no doubt, fince they came to life at the ufual time. As foon as he had performed this operation, he deferted his fituation, and died in four hours afterwards." Differtations, v. 2. § 90 and 100.

All reptiles may be faid to be oviparous; an egg, containing the germ, and as much nourifhment as is neceffary to fupport it until it is fufficiently developed to leave this abode, is formed in the body of the mother, and enters the oviduct in all. But there is a fubdivifion, according to the fubfequent progrefs of the egg thus produced. In the greateft number of reptiles, the ova or eggs are laid by the female in that ftate, and the young reptiles are developed afterwards: but in fome, as the venomous ferpents, and the true falamander, the ovum may be faid to be hatched in the oviduct, although the animals ftill come into the world fo far enveloped by the membranes, that the character of an oviparous generation is preferved. The reptiles of the latter kind are called ovoviviparous.

In both thefe cafes, a real egg, like that of birds, is produced, and has no connection with the body of the mother; it is a very different thing from the ovum of the mammiferous animals, in which there is no fupply of nourifhment for the fœtus; and the latter is connected by the umbilical chord with the veffels of the mother, and derives from this fource the materials of its growth. Here, as no true egg is produced in any part of the procefs, and as the young are always brought into the world alive, they may be juftly termed viviparous. See Lacépéde, Hift. Naturelle des Serpens, t. i. p. 31.

In ufing the common term ovum, we do not mean to reprefent that the thing produced is the fame in all; nor that it is like the egg of birds in all. There are varieties in the different orders, and, in the batracians at leaft, there is not a very clofe analogy to the ova of birds.

The eggs of reptiles are covered with a membranous, rather than calcareous fhell; but there is fome earthy matter in it. In the green turtle this fhell is flexible, but contains earthy particles. It is compofed of a foft membrane, containing albumen, which heat does not harden, and a yolk which it does. The eggs of lizards have a more or lefs hard fhell: it is flexible in the grey lizard, hard in the fcink mabouya, and the crocodile. It has been afferted, that the eggs of the iguana are not hardened by boiling. The covering of the egg is foft and calcareous in ferpents. The batracians lay gelatinous and femitranfparent eggs, without any covering.

A part, correfponding more or lefs clofely to the yolk of a bird's egg, is produced in the ovary, efcapes from its membranous covering, and enters the oviduct, where it receives its external inveftment, as the yolk of the bird's egg receives its fhell and albumen. In the turtle, the procefs feems very fimilar to what we fee in birds. There are numerous large yolks obferved in the ovarium, contained in calyces; and thefe, when boiled, are very fimilar to the yolks of birds. In the crocodile and ferpents, it is nearly the fame. But in frogs, toads, and newts, the egg in the ovary does not feem to be a yolk, but the rudiment of the tadpole; and it comes forth, furrounded by a quantity of tranfparent glutinous matter. In the toad and newt, thefe rudiments are formed into long cords by the glutinous medium, which cords are double in the toad. In the frog they come out feparately in fo many fpheres of the gelatinous matter, about the fize of large peas.

In all the reptiles which have a penis, fecundation is effected within the body; but in the batracians, which have no male organ of copulation, it occurs externally. When frogs are joined, it may be feen, that an obtufe, tumid point, occupying the place of the penis, is elongated, and brought towards the eggs neareft the vent. By taking them out of water while this laying is going on, an actual difcharge of feminal fluid upon the eggs may be feen from this point. In the fame way the male of the water newt difcharges his fluid into the water near the anus of the female, and thus fecundation takes place. Spallanzani has inftituted an immenfe number of experiments on this fubject; they prove, that if breeches be put on the frog, fo as to receive the feminal fluid, no fecundation occurs; while, on the contrary, the feminal fluid from the epididymis, or the juice of the tefticles, will produce artificial fecundation of eggs laid by the female after the male has been removed, and otherwife unproductive, or of eggs taken out of the lower part of the oviduct immediately after death. Dilution of the feminal fluid, although it diminifhed the effect of its application, did

did not altogether prevent it. When three grains of feed were added to twenty-two pounds of water, fome tadpoles were evolved in it, but much fewer than in a ftronger mixture.

As fecundation is effected in thefe animals by the feminal fluid difcharged in water, it probably is always produced by an extremely fmall proportion. Spallanzani has made fome calculations, in order to find out the expreffion in numbers of the quantity of femen that was efficacious in fome of his experiments. He mixed three grains of feminal fluid with eighteen ounces of water, and found that a globule, $\frac{1}{50}$th of a line in diameter, taken out of this mixture, was often fufficient to fecundate a tadpole. The ratio of the tadpole to the particles of feed diffufed in this drop of water, is found to be as 106,477,777,7 to one. The weight of the feed is $\frac{1}{199,468,750,0}$ of a grain, and its bulk $\frac{1}{300,212,042,0}$ of a cubic line. Differtations, v. i. § 655.

He found, however, that although fo minute a quantity of feminal fluid is fufficient to produce the effect, there muft be contact of the grofs and vifible part of the fluid; that no vapour or effluvium, no *aura fpermatica* will fuffice. Diff. ch. 5. § 161—170.

The feed of one fpecies will not fecundate another; that of the water newt has no effect on the embryos of frogs and toads; nor reciprocally: neither is there any action of the feeds of frogs on toads, nor *vice verfâ*. § 171—172.

The number of eggs is fubject to much variety: it is inconfiderable in the ferpents; from ten to twenty in the vipers and lizards; one or two hundred in the crocodile, according to Bartram, Travels in America; two or three hundred in the turtle; but the moft numerous in the frog kind. In the toad, where the eggs are laid in a double row, forming a cord of a glutinous nature, thefe rows meafured 43 Paris feet, and contained 1207 eggs. Spallanzani Diff. v. ii. § 45.

In the teftudines, ferpents, and lizards, which have a true yolk, this is to be regarded as a fupply of nourifhment for the young animal, whofe evolution probably goes on in a manner analogous to what is obferved in birds; although the procefs has not been actually watched, nor the order and fucceffion of the changes obferved, as in that clafs. Blumenbach has delineated the egg of the crocodile, with the young one coming forth; the fhell is flexible, as in the other amphibia, and confifts of a thick, leathery, and tough, external ftratum, marked throughout with extremely fine undulated lines, and lined by a more delicate fmooth membrane. The recent eggs, and the young crocodiles which they contain after evolution has commenced, are eaten by various African tribes. The relation in fize between the egg (about equal to that of the goofe), and the full grown animal (the Nilotic fpecies), which reaches to thirty feet in length, or even more, is at firft view remarkable; and Herodotus has called the crocodile the largeft animal from the fmalleft egg. (Blumenbach's Abbildungen, N° 27.) Seba has alfo figured a young crocodile, with the membrane of the yolk adhering to the abdomen, as in birds. Thefaurus, t. i. pl. 104, fig. 7.

In the animals juft enumerated, the eggs, whether depofited in the fand of the fea-fhore, or of the banks of rivers, in the holes of trees, the chinks of walls and rocks, &c. undergo no procefs of incubation like thofe of birds, but are developed in the ordinary temperature of the atmofphere, and the young animals come forth from their confinement, differing only in fize and proportions from their parents.

In the venomous ferpents, and the falamanders, the cafe is different. The egg containing, as in the preceding inftances, the young animal, and a fufficient fupply of nutriment for its growth, until it is of fize to quit its original abode, is hatched in the oviduct of the mother, and the young come forth from the cloaca alive, but furrounded by their membranous coverings. The young vipers and other venomous ferpents, when they are born, are freed by the mother from this kind of after-birth.

A very curious circumftance has been obferved in fome of thefe, recalling to our minds the abdominal pouches of the marfupial mammalia, and the mode in which they ferve as a fhelter for the young, while yet too fmall to fhift for themfelves. Palifot Beauvois thus relates the fact we allude to. "Having perceived a rattlefnake at fome diftance, I approached as gently as poffible, when, on lifting my hand to ftrike him, he founded his rattle, opened his mouth, and received into it five fmall ferpents, about the fize of a quill. I retreated and concealed myfelf, when the animal, thinking the danger at an end, opened his mouth, and let out his progeny. When I appeared again, they immediately took to their fame retreat." He had heard this fact from American planters, and it has been fince confirmed by other travellers. Daudin, Hift. Nat. des Reptiles, v. 5. p. 68.

The young of the falamander, like thofe of the viper, are born alive. The female brings forth very delicate oval vefícles, which may be compared to hydatids, each of which contains a perfect young falamander, an inch in length, moving its tail, and lacerating its coverings at the time of birth, and emerging in the form of a four-footed tadpole.

"In this fame ftrange animal," fays Blumenbach, "I have obferved a curious fact, already noticed by Wurffbain in his Salamandrologia, p. 83. *viz.* that a female, kept by herfelf, and abfolutely without intercourfe with any other of her kind, has produced young ones. I have kept in a glafs at home, for five months, a female falamander, whofe tail I had cut off, and in the mean time have had no other in the houfe, nor even feen one. Yet this folitary female, which, to my furprife, fuftained fo long a faft without growing thin, has begun within a few days to bring forth young, of which thirty-four are now before me, not only living, but very lively. This obfervation will lead us to two conclufions; 1ft, that falamanders really copulate, and that the male does not fecundate the ova as they are difcharged, like what we have defcribed in the cafe of the water newts: 2dly, that falamanders have the fame nature in this refpect as hens; which, when they have been once impregnated by the cock, will lay fruitful eggs, not for a whole year, as Fabricius ab Aquapendente afferted, but, according to the moft accurate refearches of Reaumur (art de faire eclorre les oifeaux domeftiques, t. 2, § 327), for five weeks after feparation from the male.

Thefe young falamanders have a two-edged tail, broadly pinnated on each edge, excellently adapted for fwimming, and furnifhed on each fide of the neck with fimbriated branchial appendages like thofe of the tadpole, which however foon difappear, the two-edged tail being at the fame time converted into a cylindrical pointed one." Specimen, &c. 34.

All the reptiles of the frog and toad kind, and the aquatic falamanders, have this remarkable peculiarity, to which nothing at all analogous has been obferved in the economy of the warm-blooded claffes or the fifhes: *viz.* that they undergo a metamorphofis; and have, in their two ftates, not only an altogether different external form, but alfo important differences in many of the great internal organs. In their firft ftate, they are little aquatic animals with tails and

and large heads; from their twifting movements of the former, and the great fize of the latter, they have been called in Latin gyrini, in French têtards: the Englifh name is tadpoles, and the German kaulquappen.

Developement of the Frog.—As the fpawn of frogs is depofited in ponds, ditches, or other ftagnant water, the contained ova are evolved in the ordinary temperature of the atmofphere. In one fpecies of toad, Spallanzani fays, that it proceeds at 6° above freezing of Reaumur. He found that a temperature of 111° Fahrenheit, did not interfere with the fubfequent evolution; that the number of tadpoles produced was much diminifhed after expofure to 122°; and that very few were evolved after the eggs had been immerfed in water of 132°. A heat of 111° was fatal to tadpoles and frogs; although the latter bear 111° in the warm fprings of Pifa. (Tracts, vol. i. p. 32.) Each egg lies in the centre of a tranfparent fpherical mafs of mucilage; many of which, aggregated together, form what is called frog's fpawn. Round the eggs are two concentrical membranes, of which the innermoft, when pierced with a needle, difcharges a fluid as limpid as water. The egg is round, and has a fmooth furface, of which one hemifphere is black, and the other white. When the hot feafon is far advanced, the obferver foon perceives the lineaments of the tadpole. The egg grows for fome hours without lofing its round fhape: it is next elongated; the white hemifphere becomes darker, and the black changes into a longitudinal furrow, terminated by two perpendicular proceffes. And, as it increafes in bulk as well as length, the internal circular membrane is dilated, and contains more fluid. By tracing thus the progrefs of the evolution, we come to perceive that thefe bodies are not eggs, as naturalifts fuppofe, but real tadpoles. The furrow and the proceffes become longer; the fuppofed egg affumes a pointed figure, the whitifh hemifphere dilates, and the black is incurvated. The pointed part appears to be the tail of the tadpole, and the other the body. Further, the oppofite end takes on the appearance of the head, in the fore part of which the form of the eyes is vifible, though they are yet clofed. The two proceffes alfo, by which the animal faftens itfelf to bodies, when it is tired of fwimming, become evident, as likewife the veftige of the aperture of the mouth, and the rudiments of the gills. As the organs are further unfolded, the tadpole, which has not moved hitherto, begins to ftir, and loofen its fetters; at this time it appears clearly, that the internal circular membrane is the amnios, in the liquor of which the tadpole floats; the umbilical chord at laft is feen, and becomes ftill more vifible the firft day after the animal has quitted his confinement.' The cord is not, as in other animals, attached to the belly, but to the region of the head. (Spallanzani's Differtations, v. 2. § 14—16.) We take the liberty to note what is here faid about the umbilical cord as a fubject for further refearch.

The branchiæ are vifible towards the end of the fixth day: in the courfe of the feventh and eighth all the tadpoles quit the vifcid fubftance, which had been floating on the water, and which had hitherto ferved them for food. By the fourteenth and fifteenth days they are fo much grown, that two fmall but prominent eyes, an open mouth, noftrils, &c. can be diftinguifhed. About the nineteenth and twentieth days the branchial appendages are withdrawn within the fkin, and no longer vifible. The heart can be feen to move, and the caudal vertebræ are recognifable. On the twenty-fourth day the front limbs, which had already exifted under the integuments, appear in the place of the branchiæ, or rather near where they had been. In ten or twelve days more the hind limbs come out. In this ftate they fwim about in the water, and grow. The tail gradually difappears, and in about two months after they have been hatched, they are metamorphofed into frogs. Thefe at firft are fmall, and then become gradually larger. Except in the cafe of the rana paradoxa, and the bufo fufcus, in which the tadpoles become fo large, that the animal, when it has changed, is of the adult fize.

Anatomy of the Tadpole.—The points in which the animal differs from the organic arrangements of its perfect ftate, are the large tail, which bears a very confiderable proportion to the body, and is afterwards entirely loft; comparative fmallnefs of the mouth, to the under lip of which a fmall organ is attached for fixing the tadpole to other objects; a kind of horny plate for jaws; two tuberofities under the neck, which the animal can diftend at pleafure; the rudiments of the lungs; the inteftines convoluted in a fpiral mafs, which fwells the abdomen, and far exceeds, in its ratio to the length of the body, the inteftinal canal of the perfect animal; the branchial appendages, and the veffels connected with them; the fore limbs, fituated at firft under the fkin. For the feries of changes, and the anatomy of the young animal, fee the plates of Roefel, Hift. Ranar. Noftrat.

Further particulars of the anatomy of tadpoles, and particularly of the circulating and refpiratory organs. In his "Recherches fur les Reptiles douteux," Cuvier has entered at fome length into a confideration of the anatomy of the tadpole. The following account, which is tranflated from his memoir, as publifhed in the "Recueil d'Obfervations de Zoologie et d'Anatomie comparée, faites dans le Voyage de Humboldt et Bonpand," v. 1. p. 195, is to be underftood as applying to the full grown tadpole.

The tadpoles of frogs, tree-frogs, and toads, differ from thofe of falamanders, principally in having their branchiæ concealed: we have already obferved, that in their earlier ftages the branchiæ of the former are alfo external: the only way by which the water can efcape from them is through two holes, formed in different fituations, according to the fpecies: there are even feveral which have only one hole, on the left fide. Such are the tadpoles of the jackie (rana paradoxa), and of the brown toad (buco fufcus); but the tadpole of the common frog has two, both placed below.

We find, on opening the fkin of a tadpole longitudinally, that the internal organs are divided into two parts, or contained in two membranous facs.

The firft extends from the horny and falfe jaws, which form the mouth of the tadpole, to behind the branchiæ, enveloping the latter entirely. The other contains the abdominal vifcera; it is the peritoneum, on which veftiges of the abdominal mufcles are already vifible.

The firft fac is very thin and tranfparent, and penetrated, like the fkin, by holes for the exit of the water from the branchiæ.

The latter form on each fide four tranfverfe rows of fmall tufts or fringes, fupported by the fame number of fmall cartilaginous arches, which are marked on the fide next to the mouth by fmall rounded tubercles. Thefe cartilaginous arcs are articulated on one fide behind the cranium, on the other to a fpecies of os hyoides, and have the fame motions as in fifhes. In their intervals the water can pafs freely from the mouth to the branchiæ, to be difcharged fubfequently through the fmall external apertures.

The organization of the branchiæ in the tadpoles of frogs is, therefore, the fame as in certain fifhes, for example the callionymi and others, where the water can only pafs out by narrow apertures; there is, however, this difference, that

that they are not covered, either by a branchial operculum, or by radiated bones.

The branchiæ, or gills, properly fo called, that is, the immediate organ in which the pulmonary veffels are diftributed, are fmall tufts formed like feathers, that is to fay, fringed on the two fides. Each cartilaginous arc fupports about thirty fuch; and in the middle of each tuft are its two principal veffels derived from the two great blood-veffels of the arc.

It may be obferved here, that the fifhes called fyngnathi have alfo their branchiæ in the form of tufts.

The heart, placed in front of this apparatus, and receiving the blood from the body by the vena cava, which comes, as in moft cafes, in great part through the liver, has only one auricle and ventricle, as in fifhes, and in adult frogs and falamanders, without any of thofe divifions which are obferved in the chelonian and faurian orders. The ventricle gives origin to a fingle artery, which is completely diftributed on the eight branchiæ, fo that no drop of blood can go to the reft of the body, without having paffed through the refpiratory organs. All the blood which has circulated through the gills, is collected in the branchial veins, which go towards the back, and are united into a fingle trunk, which becomes the defcending artery: but, before uniting, they furnifh arteries to the head, fore feet, lung, and liver; fo that in the tadpole, the lung receives blood which has been already expofed to the action of water; and this fmall portion of the animal's blood undergoes refpiration twice, while, with refpect to the great mafs of the fluid, there is only one refpiration, and that of an aquatic nature, or fimilar to the refpiration of fifhes.

Great changes take place when the tadpole becomes a frog; but they are produced by very fimple means. As the arms and head increafe in fize, their arteries are enlarged; the branchiæ, on the contrary, are obliterated, and their arteries are gradually reduced: but, as it is always neceffary that blood fhould go to the head and other parts, one of the four principal branchial arteries on each fide is enlarged, and ferves to convey it. Then the artery, which goes out of the heart, and was formerly divided into eight branches, is now fimply bifurcated, and its two branches fupply the arterial trunks of the head, arms, lungs, &c.; and laftly, are united to form the defcending aorta. Now this is precifely the circulation of the frog, in order to produce which it has been merely neceffary to obliterate fix of the branchial arteries of the tadpole, and to enlarge the two others. Henceforward the lungs are the exclufive feat of refpiration, receiving, however, at each pulfation, only a fmall portion of the whole mafs: the frog, therefore, is now an aërial animal in refpect to its breathing.

While thefe changes are going on in the refpiratory organs, feveral others are taking place in different parts of the body. The narrow horny bill, preceded by fmall flefhy lips, falls off, and its mufcles difappear; the jaws grow hard, and form a much more ample mouth.

The eyes, difengaged from that fkin, which only allowed them to appear through a tranfparent difk, are now feen with their complicated apparatus of three eye-lids.

The fore-feet, which had been concealed between the bag enclofing the branchiæ and the peritoneum, appear externally; the hind-legs grow every day larger; and the long tail, formed by fo many mufcular ftrata, and fupplied by fuch numerous veffels and nerves, begins to difappear. The inteftines, formerly of nearly uniform fize throughout, exceffively long and arranged in a fpiral mafs, become fhort, and are dilated at proper parts to form a ftomach and colon.

Among thefe changes, which convert the tadpole into a frog, we cannot enumerate the appearance of the generative organs. The tadpole already poffeffes tefticles, ovaries, and their fatty appendages; and if thefe parts are not fo large as in the frog at the feafon of reproduction, they approach nearly to their fize at other times of the year.

What we have juft faid concerning the tadpole of the frog is equally applicable to that of the toad; but the different fpecies exhibit confiderable varieties in the epocha and the fize at which the change occurs, as well as in the rapidity of the change. The jackie (rana paradoxa) lofes its tail very late, and long after its branchiæ; while the latter do not entirely difappear until it has reached the full fize of its perfect ftate: the pipa, on the contrary, lofes both very early, and while it is ftill very fmall. The fpecies which lofe their branchiæ late, are larger in the tadpole than in the perfect ftate, becaufe thefe fupernumerary organs fwell out the front of the body, while the tail prolongs it behind. They feem, therefore, to become fmaller under their metamorphofis, and grow no more when they have become frogs. On the other hand, thofe which lofe their tail and branchiæ early, have ftill a long time to grow, and may be feen of all fizes in the perfect ftate. This has given rife to the miftaken notion that the jackie is changed into a fifh; the tadpoles being larger than the adult frogs, it was not thought poffible that the latter could be the fecond ftate.

We might reftore to the larvæ of the falamanders the name of cordyli, which they bore among the Greeks, according to the remark of Schneider. They ought not at leaft to have that of tadpole (têtard), becaufe they have not a large head, their branchiæ not being concealed under confiderable coverings, but floating loofely on the exterior of the body. They are tufts arranged like the teeth of combs, fimply flefhy or membranous, and attached by pedicles, which allow them to float loofely in the water. The cartilaginous arcs of the fides merely ferve to limit the fmall apertures through which the water paffes out of the mouth; for, although the form and arrangement of the tufts feem to expofe them fufficiently to the action of water, there are ftill openings from the mouth, enabling the animal to eftablifh a current of the fluid. In other refpects, the circulation is carried on as in the branchiæ of the tadpoles of frogs, and it undergoes the fame changes when the branchiæ are obliterated.

The larvæ of falamanders, obferved by Cuvier, had the fame vifcera as the adult animals, and poffeffed no horny bill, although their branchiæ were ftill very complete. He therefore concludes, that in this refpect, as well as in their feet, and in the organization and permanence of their tail, there is a much more clofe refemblance between thefe larvæ and the adult falamanders, than between tadpoles and frogs.

Thefe remarks on the anatomy of the tadpole, and of the larvæ of falamanders, are illuftrated by four figures in the 13th plate of the work quoted above. Figs. 1, 2, and 3 reprefent the anatomy of the tadpole of the bufo fufcus; and fig. 4. that of the larva of the falamandra aquatica.

The co-exiftence in the fame animal of branchiæ and lungs, that is, of organs calculated for breathing air, and of thofe which are fitted to extract air from the water, is not peculiar to the larvæ of frogs and falamanders; it is obferved alfo in the firen lacertina and the proteus anguinus, two animals whofe conftruction is in many refpects fo fingular, that the opinions of naturalifts concerning them have been long extremely unfettled. Many have fuppofed them to be the larvæ of fome large reptiles, for which opinion, other

other circumſtances in their organization and habits, beſides the poſſeſſion of branchiæ and lungs, have been adduced as arguments. Others have contended that they are perfect animals; and the more exact reſearches of modern naturaliſts and anatomiſts ſeem to have finally proved that this is the caſe. The anatomical details, by which this concluſion is ſupported, will be found towards the end of the article.

As the ſiren and proteus, truly perfect animals, have been ſometimes conſidered as larvæ or imperfect ſtates of unknown reptiles, ſo the contrary error has been committed, of deſcribing the larvæ of known ſpecies as perfect animals allied to the ſiren and proteus. Laurenti, one of the firſt naturaliſts who endeavoured to reduce the claſs of reptiles to regular order, eſtabliſhed a genus (proteus) for ſuch batracian reptiles as, according to him, poſſeſſed both branchiæ and lungs. To this genus he has aſſigned the tadpole of the rana paradoxa, under the name of proteus raninus; and another, which he himſelf inſpected, and which has ſince been aſcertained to be the larva of an aquatic ſalamander, under that of proteus tritonius. (See his Specimen medicum exhibens ſynopſin reptilium.) The ſiren operculata of M. de Beauvois (Tranſactions of the Philoſophical Society of Philadelphia, vol. iv.) is conſidered by Cuvier as a ſimilar inſtance, and perhaps as the very axolotl or Mexican animal, which will be deſcribed preſently. He regards, in the ſame light, an animal deſcribed by the very learned writer on amphibia, Mr. Schneider, as found in the lake Champlain: ſee Hiſt. Amphib. Nat. et Litter. Faſcic. 1. p. 50. He ſays it may be objected that we cannot eaſily conceive that ſo complicated an apparatus as that of the branchiæ, their cartilaginous arches, and the muſcles moving them, ſhould diſappear and leave no trace behind; but, as the larvæ of our ſalamanders experience ſuch a change, the ſingularity of the phenomenon cannot be pleaded as an objection to it. Recherches, &c. p. 117.

Anatomy of the Axolotl, or large Mexican Salamandrine Tadpole.—Another animal of this kind is one found very commonly in the lake ſurrounding the city of Mexico, and noticed by the early writers in their accounts of thoſe countries, and of the intereſting objects they produce, although not methodically deſcribed or ſcientifically inveſtigated until very lately. Hernandez ſpeaks of it in two places; in one, under the name of the eatable tadpole (gyrinus edulis), or atolocatl (Hiſt. Anim. Miner. Nov. Hiſp. lib. unic. Tract. 5. cap. 4. p. 77: this book is placed at the end of the abridgement by Recchi); in the other, under that of luſus aquarum, piſcis ludicrus, or axolotl (ibid. cap. 2. p. 76, and in the large abridgement by Recchi of the whole work of Hernandez, lib. 60. cap. 4. p. 316.) This account, accompanied by a figure of ſome other animal, was copied into other works with various errors.

Dr. Shaw deſcribed an individual ſent immediately from Mexico to the Britiſh Muſeum, and gave two good figures of it; in the Naturaliſt's Miſcellany, N° 343, under the name of gyrinus mexicanus; and in the General Zoology, vol. 3. pt. 2. pag. 612. pl. 140, under that of ſiren piſciformis, conſidering it as allied to the genus ſiren.

Mr. de Humboldt met with it in Mexico, and recogniſed it as the axolotl of the Mexicans and firſt Spaniards, under which name it is ſtill known. He brought ſpecimens of it to Europe, and entruſted their anatomical inveſtigation to the experienced hand and profound judgment of Cuvier, whoſe deſcription we extract from the Recherches ſur les Reptiles douteux, already quoted, pag. 109. et ſeq. pl. 12.

Anatomy of the Axolotl.—In its ſize and general configuration it very cloſely reſembles the ſalamander terreſtris (lacerta ſalamandra) of Europe. No one would heſitate in calling it a ſalamander, were it not for the branchiæ, which latter reſemble very narrowly thoſe of the larvæ of ſalamanders, and float looſely at the ſides of the neck.

The openings communicating with the mouth are four in number, and much larger than in the ſiren. A fold of the ſkin of the head forms a ſpecies of operculum for the four. There are four arches, as in fiſhes, and we ſhould hence expect five openings, but the fourth is immediately united to the trunk. The two intermediate arches have, towards the mouth, two rows of pointed denticuli; but the firſt and fourth poſſeſs, each, only a ſingle row. None of theſe denticuli exiſt towards the operculum, ſo that the firſt of the four openings is not denticulated in any direction. Each of the four arches has, towards the outſide, a ſharp membranous criſta, which might deceive ſuperficial obſervation by cauſing a reſemblance to the gills of a fiſh; but there is no vaſcular net-work for reſpiration, and the arterial trunks follow, without any diviſion, the three firſt arches to arrive at the branchial tufts, which are the only true gills. There are three of theſe tufts on each ſide, attached to the three firſt arches, where the ſkin joins them together; the operculum and the fourth arch have none. Theſe tufts are much more ramified than thoſe of the ſiren, but their ramifications reſemble a lock of hair, and are not arranged with ſo much regularity.

Oſteology.—The head is the ſame as in the ſalamanders, except that the cranium is rather broader. The teeth are placed in the ſame way on the edges of the jaws; there are moreover two plates immediately behind the edge of the upper jaw; but the two longitudinal ſeries, which are obſerved along the palate of the European ſalamanders, could not be perceived. The head is articulated in the atlas by two condyles, as in the ſiren and ſalamanders.

The apparatus for ſupporting the branchiæ is very ſimilar to that of the ſiren; and, at the time of the metamorphoſis, a part of it probably remains to form the os hyoides of the ſalamander. The middle piece is cylindrical, ſhort, and terminated behind by a forked extremity. The front end ſupports two cartilages, the ends of which, ſuſpended to the angles of the jaw, correſpond to the hyoideal branches of fiſh: they are immediately under the membranous operculum. From the poſterior end of this middle piece proceed two other branches on each ſide; a broad one ſupporting the firſt cartilaginous arch, and a more ſlender one trifurcated to ſupport the three other arches. The four branchial arches are ſuſpended, by their outer extremities, to the firſt vertebra.

There are ſeventeen vertebræ from the head to the pelvis; and twenty-three from the latter to the end of the tail. The ſpinous proceſſes of both are longer than thoſe of the ſalamander; and they exiſt on both aſpects of the caudal vertebræ, which makes the vertical meaſurement of this part exceed that of the European aquatic ſalamanders.

There are thirteen ſmall ribs on each ſide, ſimilar to thoſe of the ſalamander.

The oſteology of the limbs reſembles in all reſpects that of the ſalamander, excepting the more pointed form of the laſt phalanges, which has occaſioned them to be taken for nails.

Organs of Senſe.—The eye is ſmaller in proportion than in European ſalamanders; but not ſmaller than that of the ſpecies brought from the Alleghany mountains by Michaux.

Organs of Circulation.—The vena cava receives the termination of the veins of the head; of the branchiæ, and their arches; of the lungs; of the fore-feet; laſtly, of the inferior vena cava, which has traverſed the liver, and received, as

 uſual,

ufual, the blood of the vena portarum. It enters a large and fingle auricle ; there is alfo a fingle ventricle, giving origin to a large mufcular artery, fimilar in all points to that of fifhes, of the firen, and of tadpoles. It produces for the branchiæ three arteries on each fide, which proceed, as we have already mentioned, along the three firft arches. The branchial veins are quickly united behind into a fingle trunk, under the back of the head, and this veffel, following the direction of the fpine, becomes the great artery of the body. This is exactly the circulation of the batracian larvæ ; and the axolotl, being larger than any of the European fpecies, affords a convenient opportunity of examining this kind of arrangement in the circulating organ.

Organs of Refpiration.—The branchiæ of the axolotl, exhibiting on a larger fcale the fame motions as thofe of the falamandrine larvæ, the mechanifm can be better underftood ; and the following defcription of the mufcles will, therefore, be received with intereft.

Each of the cartilages analogous to the hyoideal branches has a very ftrong mufcle, defcending from the bafis of the fkull along their convex fides to their inferior extremities. Thefe mufcles open the branchial arches, by feparating their inferior extremities from the palate.

The arches are approximated by a mufcle fixed behind to the inferior extremity of the laft, advancing under that of the three others, and giving a flip to each. Its antagonift is a fmall mufcle, fixed, on one fide, to the inferior extremity of the hyoideal branches ; and proceeding backwards as far as under the firft branchial arch, to which it is attached, oppofite to the flip of the preceding.

The os hyoides is carried forwards by two genio-hyoidei, and backwards by two pubio-hyoidei : which latter fupply the place, as in the falamanders, both of the fterno-hyoidei and recti abdominis. It is elevated by a mufcle fimilar to the mylo-hyoideus of the fame animals.

Laftly, the three tufts are themfelves elevated and depreffed by as many pairs of mufcles, which are attached above and below to the convexities of the branchial arches, and have their other fixed points in the bafes of the tufts.

The lungs are two large bags, on the internal furface of which the blood-veffels form a loofe but very confpicuous net-work. There are no cells. They open into a common, membranous, opaque, and tolerably wide canal, fupplying the place of trachea, but unfurnifhed with cartilaginous rings, and contracted to form a fmall larynx with two membranous lips. The glottis is fmall, formed by two membranous projections, behind each of which is a fmall hollow or ventricle, which may be fuppofed to produce a more powerful voice than that of the firen.

Organs of Digeftion.—The tongue poffeffes but little power of motion ; it is free in front, but fixed behind to the anterior extremity of the os hyoides.

The œfophagus is fhort, folded longitudinally, and continuous with the ftomach, which is large and membranous, but confiderably narrowed, and more mufcular towards the pylorus. It was filled, in the two individuals from which this defcription was drawn up, with frefh-water cray-fifh, like the European, which had been fwallowed without maftication, fo that entire limbs were found even in the rectum.

The inteftinal canal is tolerably large, particularly behind, and of moderate length. It makes two principal folds, and has neither cæcum nor any internal valve. The liver is rectangular, without any deep notches ; no gall-bladder was obferved. There is a fmall fpleen in the centre of the mefentery, which is fimple, as ufual.

All thefe inteftines are like thofe of the falamander.

Generative Organs.—The ovaries, fmall, flaccid, and hardly containing vifible ova, refemble, in their fituation and fatty appendices, thofe of the falamander. The oviducts were fo delicate, that they could fcarcely be feen.

From all the circumftances juft detailed, and from the clofe refemblance of all its organs to thofe of falamanders, and their larvæ, we may conclude, that the Mexican axolotl, or firen pifciformis of Shaw, is the larva of fome large falamander.

Growth.—The age of puberty feems to be the limit of growth in many of this clafs, as in birds, and we may almoft fay, in all mammalia. But others, particularly the crocodiles, turtles, and ferpents, grow conftantly ; of which continual increafe the whales feem to afford an example among mammalia ; at leaft, no limits can at prefent be affigned to their ftature. We know little about the length of life of the amphibia. Many, particularly the tortoifes, ferpents, and crocodiles, are prodigioufly long-lived ; coming forth originally from an egg, which is very fmall in comparifon to their future ftature, growing very flowly, and reaching an immenfe fize. Niebuhr faw at Surat a tortoife 125 years old.

Organs of the Animal Functions.

Organs of Motion. Defcription of the Bones.—We know of nothing peculiar in the organifation of the bony fubftance of reptiles. In the larger fpecies, the bones poffefs as much firmnefs as in the mammalia ; but in the fmaller, as the frogs for example, they are more cartilaginous. Cuvier ftates, in general, that the bones of reptiles contain more gelatine than thofe of the mammalia. Caldefi afferts, that there are no medullary cavities in the tortoife ; according to Cuvier, there are confiderable ones in the crocodiles. Leçons d'Anat. Comp. tom. i. p. 110. They have never been feen tinged with madder.

The Head.—A very diminutive cranium, and enormous jaw, make up the head in this clafs.

As the brain of reptiles and fifhes occupies only a fmall part of the cavity of this cranium, no important confequences can be deduced from its fhape and fize. In the tortoife, this cavity is large, narrow from right to left, elevated anteriorly and depreffed pofteriorly. Its lateral parietes are almoft vertical, and its bafe is parallel to the palate. The external form of the head, and its apparent magnitude, are occafioned by the acceffory bones, between which and the cranium there is a large fpace occupied by mufcles and glands. The greateft part of the fkull is occupied by the large lateral hollows, holding the eye, and the powerful mufcles, that move the lower jaw.

The fmall fize of the cavity of the cranium, with refpect to the external bulk of the head, is ftill more extraordinary in the crocodile. In an individual four metres long (between thirteen and fourteen feet), that cavity will hardly admit the thumb, and the area of the fection of the cranium is not one-twentieth part of that of the whole head. (See a fection of the fkull of a crocodile in the Annales du Mufeum, tom. x. pl. 4. fig. 5.) The length of the cranium is not one-fifth of the length of the head in the gavials (longiroftres, Cuvier) ; and it is lefs than one-fourth in the alligators or caimans (alligatores, Cuv.), and in the true crocodile (crocodili, Cuv.) The figure of the fection is oblong, rather larger anteriorly, and defcending pofteriorly. There is a confiderable depreffion for the pituitary gland. Its breadth is equal to its height ; and the lateral parts of the head, as in the tortoife, cover only the temporal foffæ.

The relative fize of the cranium and jaws undergoes a very remarkable change, in proportion to the gradual developement of the crocodile. The head, when it comes out of the fhell, is thick and rounded, and the forehead prominent ; fee Seba.

Seba, Thefaurus, tom. i. pl. 104, figs. 3 and 6; and Blumenbach's Abbildungen, N° 27. The eyes are now equidiftant from the end of the fnout, and the pofterior extremity of the head; of which the cranium forms nearly one-third. When we look at the adult animal, we are aftonifhed to find the frontal prominence gone, leaving the head quite flat, and the jaws fo elongated, that the eyes are three times farther from the end of the fnout than from the back of the head; and the proportion of the face to the cranium is 20 inftead of 3 to 1. Geoffroy St. Hilaire in the Ann. du Muf. vol. x. p. 77.

The cameleon exhibits alfo a great difproportion between the cranium and the reft of the head. Its brain, according to the defcription of the Parifian diffectors, does not feem larger than a pea; and the remainder of the head, which is of confiderable fize, confifts of the large maxillary bones, the orbits, and immenfe temporal foffæ, which, not being feparated by any partition, give the cranium a very fingular appearance. Defcription Anat. d'un Cameleon, &c.; or Blafii Anat. Anim. vol. i. p. 14.

The cranium of frogs and falamanders is almoft prifmatic.

The French naturalifts have furnifhed excellent defcriptions and engravings of the heads of various crocodiles. It will be as well for us to enumerate here the fources of information concerning the ofteology of this animal altogether, and to give a few references to good figures of the fkeletons of other reptiles.

There are tolerably good reprefentations of the crocodile's fkeleton (the Eaft Indian) in Grew's Mufeum Societatis Regiæ, and in Faujas St. Fond, Hiftoire de la Montagne de St. Pierre de Maeftricht, pl. 44. The head of the crocodile of the Nile (croc. vulgaris, Cuvier), is figured by Geoffroy in the Annales du Mufeum, vol. ii. pl. 37, fig. 2. In pl. 4. vol. 10. of the fame work are four figures of the fkull to illuftrate a paper of Geoffroy St. Hilaire, entitled "Determination des Pièces qui compofent le Crane des Crocodiles;" and pl. 1, of the fame volume, contains nineteen figures of the heads of various crocodiles in different views, to illuftrate Cuvier's paper "Sur les differentes Efpèces de Crocodiles vivans & fur leurs Caractères diftinctifs." In the 12th volume of the Annals, Cuvier has given his "Obfervations fur l'Ofteologie des Crocodiles vivans," with two plates, in which moft of the bones are carefully figured. For the fkeleton of the tupinambis, fee Cuvier, Leçons, v. 5. pl. 3; of frogs, Roefel, Hiftoria Ranarum Noftratium; of the falamander, Latreille, Hift. des Salamandres de France; of the tortoife, falamander, frog, cameleon, lizard, and a ferpent, Daudin, Hift. Nat. des Reptiles, vol. 1; of the proteus, firen, and Mexican axolotl, Humboldt, Recueil d'Obferv. de Zool. &c. t. 1; of the tortoife, Blafii Anatomia Animalium; Cuvier, fur les offemens foffiles; and Geoffroy St. Hilaire, fur les tortues molles, in the Annales du Mufeum, vol. 14. The fkeleton of the tortoife is alfo figured in Chefelden's Ofteology; in Coiter's Lectiones Fallopii de Partibus fimilaribus, fol. Norib. 1575; and in J. D. Meyer's Zeitvertreib mit Betrachtung curiofer Vorftellungen allerhand Thiere. t. 1. tab 29, 31; t. 2. tab. 62; and the feparate parts in Caldefi offervazioni anatomiche intorno alle Tartarughe. Firenze, 1687. The fkeleton of the common green lizard may be feen in Coiter, pl. 4; in Meyer, t. 1. pl. 56; that of the falamander and water newt, and of feveral fnakes in Meyer: that of the cameleon is prefixed to Chefelden's 6th ch. Schneider has figured that of the rana pipa in his Hiftor. Amphib. fafcic. 1.

For the form of the head in the different fpecies, a point belonging rather to natural hiftory than comparative anatomy, we muft refer to the figures already quoted. The furface is more or lefs rugous in different fpecimens; and in many very confiderably fo; thefe differences are fpecific, only where individuals of the fame age are compared, for the rugofities increafe in fize and prominence in each fpecies with the increafe of years. The bony fubftance is often perforated by many fmall holes, as if it were carious or worm-eaten. The futures are conftant; they are not effaced in the oldeft heads obferved by Cuvier.

The Cranium.—The cranium of the crocodile, viewed from behind, has the form of a very irregular truncated pyramid; of which the point or narroweft portion is downwards, and the bafe excavated to lodge the brain, is upwards. This pyramid has three furfaces, one pofterior, which forms the occiput, and two lateral. The occipital furface is almoft triangular; one of the angles (the apex of the pyramid) is inferior, the other two are fuperior, and greatly prolonged backwards and to the fide, in order to form the enormous articular proceffes, which receive the lower jaw. Their pofition is almoft horizontal. The foramen magnum is fituated in the middle of this furface, and under it the fingle condyle for articulating the head with the vertebral column.

The futures depart from the foramen magnum, which divide the occiput into particular bones. The fuperior part of the cranium is formed by a fingle parietal bone. Anterior to it there is an os frontis, alfo fingle, which forms the roof of the orbits.

The offa temporum are fituated on each fide of the parietal bone, and are partly fupported by that articular procefs for the lower jaw, already mentioned.

A fmall arch on each fide, different from the zygoma, leaves between it and the parietal bone a large round hole, which perforates the temporal foffa. The arch is partly formed by a procefs of the os temporum, and partly by a particular bone articulated to the junction of the parietal and frontal. The particular bone occupies the place of the poft-orbitar procefs of the os frontis in the mammalia; for it defcends behind the orbit to join the cheek-bone; and with it finifhes the frame of the orbits.

The unufual configuration of the whole head in the crocodile neceffarily involves very extraordinary modifications of the individual bones, which it is in many cafes exceedingly difficult to refer to their correfponding ones in the crania of the mammalia. For a more minute account of this matter, which could not be eafily underftood without plates, we refer to the memoirs and engravings, already quoted, of Geoffroy and Cuvier.

A cranium fimilar to this of the crocodile, is found in the other lizards, notwithftanding the great differences in the form, proportion, and the direction of the parts. In the cameleon, therefore, the foramina, by which the temporal foffa communicate with the cranium, are fo large, and the bony edges which form them fo thin, that the latter reprefent three flender branches rifing to fupport the kind of helmet which diftinguifhes this animal. The articular proceffes are not directed backwards, but downwards.

The laft peculiarity is alfo obferved in the other lizards, but they have not the crefts of the cameleon, and the upper part of their cranium is broad, like the crocodile.

In frogs and falamanders the cranium is nearly of a cylindrical form, flat fuperiorly, and enlarged pofteriorly; the frontal bones have the fhape of an elongated rectangle, and occupy the interval of the orbits. The Surinam toad has the cranium much flatter than the other genera.

The eminences intended to affift in the articulation of the jaw are turned directly towards the fides.

The

The ftructure of the cranium of tortoifes bears more refemblance to that of crocodiles than of frogs. The frontal bones form only the roof of the orbits, and the cranium does not pafs between thefe cavities. They are very fhort, and the parietalia are three times longer. The latter are not confined to covering the cranium. They extend on each fide, and form an arch over the temporal foffa. In the fea tortoifes this arch is completed by two peculiar bones, which extend from the os parietale to the zygoma, and the anterior of which bounds the orbit behind.

The articular proceffes are directed downward, as in the cameleon. Above thefe and the meatus auditorius, we find confiderable maftoid proceffes, which are pointed fuperiorly in land tortoifes, but are rounded and marked by a longitudinal furrow in the fea tortoifes.

Serpents have two frontal bones almoft fquare, and a fingle parietal bone. Their cranium advances forward between the orbits, as in frogs. The occipital bone has a procefs directed backward, and connected with a particular moveable bone, analogous to the fquare bones of birds, to which the lower jaw, and the arches which form the upper, are articulated.

The general form of the cavity of the cranium of reptiles is oblong, and almoft of an equal breadth, being merely a little contracted between the ears. The tortoife has a kind of fella turcica, the four clinoid proceffes of which are directed forward. The fphenoidal foffa is fomewhat depreffed in the ferpents, but it has no clinoid proceffes. It is a femilunar depreffion, the plane of which is fituated from before backwards.

The bafilar foffa is lower than the other foffæ in the crocodile, and in fome tortoifes.

Foramina of the Cranium.—The interior part of the cranium is frequently not clofed by offification in reptiles and fifhes, and the olfactory nerves pafs through a large vacant fpace, which is not fubdivided into particular holes. This at leaft is the cafe with the cameleon, the iguana, tortoifes, the pike, the anarrhichas, &c. In others, the olfactory hole is contracted, but is ftill fimple, as in the crocodile. It is double in frogs and falamanders. The rays and the fharks have alfo two holes, which are confiderably removed from each other.

The optic holes are likewife fometimes united into one, as in the crocodile: thofe of the tortoife are much removed from each other, and are diftinguifhed from the great hole in the front of the cranium, by only a fmall bony partition. The ftructure of the cranium in the pike is fimilar. In the frogs, the rays, the anarrhichas, and it fhould feem in the greater number of fifhes, the optic holes are at a great diftance from each other, and perforate the fides of the cranium. Thefe animals have no fpheno-orbitar fiffure, and the fmall nerves tranfmitted to the eyes pafs each through a particular foramen.

There is, in general, only one hole on each fide for the three branches of the fifth pair of nerves, which, therefore, fupplies the place of the foramen rotundum, foramen ovale, and in part of the fpheno-orbitar fiffure. This hole, however, is divided into three in the carp.

The meatus auditorius internus exifts in reptiles.

The Face.—In the crocodile the face refembles one-half of a cone irregularly flattened on its convex furface. It is chiefly formed by two offa maxillaria, and two offa nafi, which are fituated almoft parallel to each other, and two offa intermaxillaria, which form the end of the muzzle, and furround the aperture of the nofe like a ring.

The bones analogous to the lacrymalia are four in number, two on each fide. The os malæ, which is very large, after forming the inferior, and affording a fmall procefs to the pofterior edge of the orbit, extends directly backwards to join the great maftoid protuberance: thus the temporal foffa has no communication outwardly; except by a hole which is fmaller than the orbit, and the greater part of which is covered by thefe bones, as by an arch.

The nafal foffæ are continued in a long and narrow tube under the foramen magnum. They perforate the offa palati, and a particular bone which is analogous to the pterygoid proceffes of the os fphenoides. This bone is fituated almoft precifely under the cranium, and is enlarged on each fide until it forms a kind of fquare and almoft horizontal wing. An offeous branch unites it laterally to the os maxillare and os malæ, in fuch a manner that a large hole is left on each fide of the arch of the palate.

In the cameleon the face is concave fuperiorly, and bordered by a ferrated ridge throughout the whole of its circumference. We obferve two holes which communicate with the orbits, and two other oval foramina, which correfpond to the incifive holes in the palatine furface. The bones which compofe the face are nearly the fame as thofe of the crocodile. The other lizards exhibit ftill lefs difference.

The frog and the falamander have the nafal and intermaxillary bones very fhort, and broader than long, which renders their face round anteriorly. The os maxillare is very narrow, and is fcarcely contracted in forming the zygomatic arch. The orbits are large, but have no inferior furface, and therefore communicate with the palatine foffa. The offa palati form the anterior edge of the orbitar foffa inferiorly. They refemble portions of a circle. They are furnifhed with pointed teeth on their circumference. The canal of the nares is very fhort in the falamander. There is only a fimple hole in the frog.

The face of the Surinam toad is very flat, but the bones are the fame as in the frog. The orbitar foffæ are oval, and no aperture fimilar to the canal of the nares can be diftinguifhed.

The face of ferpents is rounded nearly in the fame manner as that of lizards. Between the os frontis and os parietale, there is a particular bone which terminates the frame of the orbit pofteriorly. Thefe animals have no os malæ. We can, however, eafily diftinguifh two offa nafi, two offa maxillaria fuperiora, two offa intermaxillaria, and fome analogous to the palatine arches of birds, which are furnifhed with teeth, and which are articulated to the bone which fupplies the place of the os quadratum, with refpect to the lower jaw. Two particular bones unite thefe arches to the maxillaria fuperiora.

In thofe that have teeth, or poifonous hooks, as the viper, the rattlefnake, &c. there are befides two fmall peculiar bones, articulated and moveable, which fupport thofe teeth. They are fituated upon the intermaxillary bones and the anterior extremity of the offeous branch, which joins the fuperior maxillary bone to the arch of the palate.

The face of the tortoife is circular before, and rounded on every fide. It is compofed of nearly the fame bones as that of the crocodile. The intermaxillary bones are, at a very early period, confolidated with thofe of the upper jaw. The bones analogous to the os malæ are three in number, one articulates with the os temporum and with the two others; it is fituated pofteriorly, and forms the zygomatic arch. The other two portions are received on its anterior extremity; one extends upwards, and unites with the orbitar angle of the os frontis; the other is directed

downward,

downward, and articulates with the pofterior and external procefs of the os maxillare fuperius.

The offa palati are broad, and form the pofterior arch of the nafal foffa.

The bones of the face of tortoifes commonly cover each other at their edges, which are refined into thin laminæ. It is therefore very difficult to diftinguifh the futures.

In the fea tortoifes the temporal foffæ, which are very deep, are covered by an offeous lamina, which forms a very folid arch above them.

The defcription of the jaws, and the temporal foffæ, is given at the beginning of the account of the digeftive organs.

Cavities of the Face.—1. *Nafal Cavity.* It is a broad fpace in the tortoifes, occupying the whole thicknefs of the fnout in front of the eyes, and very fhort from before backwards. Its front opening is large, and nearly fquare, with its plane but little inclined; furrounded by fix bones. There are two round openings behind, correfponding nearly to the middle of the palate.

In the crocodile it is a long and narrow canal, extending from the end of the fnout under the occiput: its bony opening, formed entirely in the two intermaxillary bones, is turned upwards.

Other lizards have the nafal apertures fituated nearly as in birds: that is, the front or outer on the fide of the fnout, and the back or inner in the middle of the palate. They are ftill fhorter in the frogs.

2. The orbit is never feparated from the temporal foffa in reptiles by a partition, but merely by a bony branch; and even this is complete only in the lizards and tortoifes, not in the frogs, falamanders, or ferpents. The plane of its margin is lateral in the tortoifes, ferpents, and cameleon; it is more or lefs directed upwards in the crocodile, falamanders, and frogs. The figure varies from circular to triangular. The inferior furface or floor is never complete: either it is altogether deficient, or it is perforated by a very large aperture. The fame remarks are applicable to the inter-orbitar feptum.

The zygomatic foffæ are fpoken of in the defcription of the jaws and their movements, under the divifion of *Organs of the Vital Functions.*

Foramina of the Face.—Where there is no diftinction between the orbit and temporal foffa, the fpheno-maxillary fiffure is of courfe wanting. There are no internal orbitary holes, as the relation between the orbits and nofe is altogether different from what is obferved in the mammalia.

The crocodile, frog, and falamander, poffefs a large foramen incifivum. The tortoife has two fmall ones: the ftructure of the lizards is not known.

There is no fuborbital opening, reptiles having no lips to receive the artery and nerve, which it tranfmits in the mammalia.

The fpheno-palatine canal appears as a fimple hole in the os palati.

Motions of the Head.—The articulation of the head of reptiles is confiderably behind, but the motions vary in different fpecies.

In the crocodile there is only one condyle, fituated at the under fide of the foramen magnum: the atlas is formed of two portions; the pofterior is fhaped like the fegment of a ring; the anterior, which is thicker, receives the condyle, and is articulated to the fecond vertebra: there are two lateral proceffes, long, flat, and turned backward, which fupply the place of tranfverfe proceffes.

The odontoid procefs of the fecond vertebra is fhort and thick; it is articulated within a cavity in the body of the atlas. This fecond vertebra has tranfverfe proceffes fimilar to thofe of the firft.

All other lizards have nearly the fame conformation; but the condyle feems divided in two by a longitudinal fuperficial furrow.

The tortoifes have likewife only one condyle. In the land fort it is prolonged, and divided into two, as it is in the lizards. In the marine fpecies it prefents three articular faces, like a trefoil leaf. As this condyle penetrates deep into the correfpondent cavity of the atlas, the lateral motion of the head is much confined. The other motions of the head of the tortoife are thofe of projection and retraction; they depend upon the flexion and extenfion of the cervical vertebræ.

The frog, the toad, and the falamander, have the head articulated by two condyles upon the firft vertebra, which is almoft immoveable.

Serpents have three furfaces, in the manner of a trefoil, clofe together, upon one condyle, beneath the occipital foramen. The head is not more moveable on the atlas, than the reft of the vertebræ are upon each other.

Bones of the Spine.—The number of vertebræ, and every other attribute of the fpine, are more varied in this clafs of animals than in any other.

In the tortoifes, feven vertebræ are affigned to the neck: the firft is only a fingle tubercle, the annular portion of which is very diftinct. The furface, by which it is articulated with the head, is formed of three planes; one anterior, and two lateral. The point in which they unite is the moft prominent, and to this is attached a ftrong ligament. The furface which unites it to the next vertebra is a glenoid cavity; the fecond and the following vertebræ have a prominent longitudinal ridge upon the fore-part of their body. The articular proceffes defcend below the body: there are no fpinal proceffes, except one to the fecond vertebra, which points forward, and one to the third in the form of a fimple tubercle. The two laft vertebræ, at a certain age, become anchylofed. There are eight dorfal vertebræ; but they are all anchylofed, together with the ribs and the back-fhell, in one immoveable piece. They have, therefore, neither proceffes nor articular furfaces: they are all narrower in the middle than at the ends. The lumbar and facral vertebræ are likewife confolidated with the back-fhell, but thofe of the tail are free and moveable. The condyle, which forms the body of thefe vertebræ at its articulation with the others, inclines backward, and not towards the head, as thofe of the neck do. There are likewife upon the fore-part of the body, at its bafe, two fmall tubercles; but all the proceffes of thefe vertebræ refemble thofe of the mammalia.

In the family of lizards, the crocodile has feven cervical vertebræ, diftinct indeed, but fo clofely articulated as not to be moveable. The proceffes are fo numerous, long, and clofe, that the animal cannot bend its neck, and the cervical column may, therefore, be regarded as a fingle piece. This correfponds with the reports of travellers, that the crocodile is unable to turn his head round. The anterior furface of the body is concave, and the pofterior convex, throughout the vertebral column of the crocodile. The atlas is compofed of fix pieces, which appear to continue feparate through life: the vertebra dentata has five only. The other cervical vertebræ have on each fide two fhort tranfverfe proceffes, which ferve to fupport the fmall ribs or appendices, which limit the flexion of the neck. Each has two pedicles, attached to the two proceffes juft mentioned: the appendix projects into a fharp procefs before and behind, which touch thofe of the contiguous vertebræ. The five firſt dorſal vertebræ have a lateral tubercle for the head of the rib, and another on the tranſverſe proceſs for its tubercle: thus the rib is articulated only to one vertebra. But the firſt of theſe articular ſurfaces is wanting in the remaining ribs, while each of their tranſverſe proceſſes has two articular faces. The ſame number (ſeven) is found in moſt lizards, though the cameleon has only two. The ſacral vertebræ are very few in every ſpecies, and none of them have a large os ſacrum.

As frogs have no ribs, no diſtinction can be formed with reſpect to the three firſt orders of vertebræ in them. They have in general eight between the neck and the pelvis, all furniſhed with pretty long tranſverſe proceſſes. The laſt are the longeſt, and touch the oſſa ilii. In the toads, the tranſverſe proceſſes are very large, and ſhaped like hatchet blades. The os ſacrum conſiſts of a ſingle bone only: it is long, pointed, compreſſed, and has no coccyx. In the pipa, which has the tranſverſe proceſſes of the ſecond and third vertebræ much longer than the others and almoſt like ribs, this bone is oſſified with the laſt vertebræ.

The ſalamanders have fourteen vertebræ between the head and the ſacrum; they have all nearly the ſame ſhape, except the firſt, which receives the head, and the laſt, which is articulated to the ſacrum. The two extremes of the ſpine alone want the veſtiges of the ribs, which conſiſt of ſmall oblong moveable bones, actually articulated to the tranſverſe proceſſes, which here take a poſterior direction. The articular proceſſes are large, and wedged together. The poſterior reſt upon the anterior, ſo as to impede the motion of the ſpine backward. The ſacrum conſiſts only of a ſingle vertebra, but there are twenty-ſeven in the tail.

In ſerpents, the vertebræ alone conſtitute almoſt the whole ſkeleton. It appears in general, ſays Blumenbach, that the number of vertebræ, in red-blooded animals, is in an inverſe proportion with the ſize and ſtrength of their external organs of motion. Serpents, therefore, which entirely want theſe organs, have the moſt numerous vertebræ; ſometimes more than three hundred. (Comp. Anat. p. 118.) In confirmation of this remark, we may obſerve how numerous the vertebræ are in the elongated fiſhes, as the eel, and in the whales, as the porpoiſe, (above one hundred in the former, and between ſixty and ſeventy in the latter). Birds, whoſe wings give them ſuch vaſt power of locomotion, have very few vertebræ, if we conſider the anchyloſed ones as forming a ſingle piece; and the frog, with its immenſe hind extremities, has a very ſhort ſpine, conſiſting of ſtill fewer pieces than that of birds. The vertebræ of this order are nearly of the ſame form, from the head to the tail: the body, as well as the ſpinous, articular, and tranſverſe proceſſes, are eaſily diſtinguiſhed. In certain kinds, for inſtance the boæ, the ſpinous proceſſes, which are continued throughout the whole length of the back, are ſeparated from each other, and allow reciprocally a motion ſufficiently conſpicuous. Wherever this diſpoſition of the ſpinous proceſſes prevails, the body of the vertebræ, on the ſide next the belly, preſents only an obſcure projecting line. In other kinds of ſerpents, as for example the rattleſnake, the ſpinous proceſſes are long, and ſo large as to touch each other. They have, for their baſis, the articular proceſſes, which lie on each other like tiles. In conſequence of this ſtructure, the motion of the ſpine towards the back is very circumſcribed, but its motion towards the belly and ſides much augmented. The bodies of the vertebræ play very eaſily in theſe directions upon one another, and are armed with a ſharp ſpine tending towards the tail, which only obſtructs their motion when it might produce a luxation. The firſt vertebræ differ from thoſe of the reſt of the body, only in having the rudiments of the ribs much ſmaller: there is no neck in theſe animals. The vertebræ of the tail differ no farther than in having no ribs, and that their ſpines, both ventral and dorſal, are double, or form two ranges of tubercles. The articulation of the bodies of the vertebræ with each other is very remarkable: the anterior part of the body of the vertebra preſents a ſmooth hemiſpherical tubercle, and the poſterior part a correſponding cavity; ſo that each vertebra becomes connected to thoſe next it by a ſort of knee-joint. This mode of articulation fully explains the motion of reptiles, which is performed winding from ſide to ſide, and not up and down, as it is repreſented by painters.

Table of the Number of the Vertebræ in Reptiles.

I. Oviparous Quadrupeds.

Species.	Vertebræ of the Neck.	Vertebræ of the Back.	Vertebræ of the Loins.	Vertebræ of the Sacrum.	Vertebræ of the Tail.
Turtle - - -	7	11	0	3	20
Crocodile - -	7	12	5	2	34
Tupinambis -	7	18	4	2	104
Iguana - - -	5	11	9	2	72
Cameleon - -	2	17	3	1	69
Salamander - -	1	12	1	1	26
Frog - - - - 10 in all.					
Pipa or Surinam toad, 8 in all.					

II. Serpents.

Species.	Vertebræ to which Ribs are joined.	Vertebræ of the Tail.
Viper (berus) - - - -	139	55
Spectacle ſnake (naia) -	192	63
Garter ſnake (natrix) - -	204	112
Amphiſbæna - - - -	54	7
Boa (conſtrictor) - - -	252	52
Common ſnake - - - -	244	More than 60.
Rattleſnake - - - -	175	26
Slow worm (anguis fragilis)	32	17

Of the Ribs and Sternum.—The thorax of reptiles is very various in its ſtructure. Frogs have a ſternum, but no ribs; ſerpents have ribs, but no ſternum; tortoiſes have the ribs oſſified to the back-ſhell, and the ſternum included in the breaſt-plate; the crocodile and lizard have perfect ribs, but their ſternum is almoſt entirely cartilaginous. In the crocodile, the firſt portion of the ſternum is oſſified and elongated. It receives the two clavicles. The remaining part is entirely cartilaginous. It is united with the os pubis, and ſends off eight cylindrical cartilages to the parietes of the abdomen. This ſtructure, conſtituting a ſpecies of abdominal ſternum, apparently for ſupporting the viſcera, is quite peculiar to the crocodile. The ribs are twelve in number, the two firſt and two laſt of which are not attached to the ſternum. The intermediate ribs have upon their poſterior edges cartilages partly oſſified, which ſupply the place of the angles of the ribs in birds. All the poſterior ribs, beginning at the fifth, are only articulated to the tranſverſe proceſſes of the vertebræ, which are of great length. The five firſt articulate with the vertebræ at two points, one on its

its body, and the other on the tranfverfe proceffes. The iguana and the tupinambis have only the upper part of the fternum offified: it is broad, and receives fix ribs and the clavicles; the other ribs are free. The cameleon poffeffes likewife the upper portion of the fternum; but almoft all the ribs have cartilages, which extend to the middle line, and are there united to the oppofite ones. Frogs, though they have no ribs, have neverthelefs a very confpicuous fternum. It forms on the anterior part a cartilaginous appendix, furnifhed by a difk fituated below the larynx. It next receives the clavicles, and then expanding, it terminates at laft in another difk fituated under the abdomen, and which affords an origin for mufcles. There is a peculiar bony cyft of unknown ufe on the internal furface of the fternum, in the rana pipa.

The falamander has ribs, fo fhort that they feem to be the tranfverfe proceffes of the vertebræ; they have only one point of articulation, upon which they have but little motion. Thefe rudiments of ribs are twelve in number on each fide. This reptile has, properly fpeaking, no fternum, but its place is partly fupplied by the bones of the fhoulder, as we fhall prefently fee.

The fkeleton of the chelonian reptiles exhibits to us what appears on the firft view as a completely anomalous organization. In the bony houfe which thefe animals carry about with them, there is fuch a deviation from the ordinary figure, connection, and pofition of the parts, compofing the fkeleton of other vertebral animals, that a hafty view would lead us to infer that the general model to which Nature in all her modifications of form and pofition ever adheres, has been completely loft fight of, and another fubftituted in its place. This inference would be altogether incorrect: a more accurate examination enables us to difcover in the external bony fhells of thefe fingular creatures, all the offeous pieces which belong to the cheft of a mammiferous animal or bird; fo that no effential part is wanting in their thorax, and the fingularity depends merely on the more or lefs complete offification of the whole pectoral cafe, and the peculiar forms refulting from this circumftance. Thus, inftead of the anomaly, which a hafty glance leads us to anticipate, we actually difcover, on the contrary, a new proof of the conftancy, with which an original model is retained throughout whole claffes of animals, even under the wideft differences of external form, as if Nature, having fixed on one general principle of organization, would not be at the trouble of inventing others, but rather chofe, by the ftrangeft modifications, to accommodate the organs to new fituations and forms. It is a new illuftration of that principle, in conformity to which the fin of a whale contains all the bones of an upper limb of a quadruped, the wing of the bat the regular digital phalanges, the fin of a penguin or feal the ufual bones of the extremities of a bird or mammiferous animal, &c.

The bones of the cheft in the tortoifes form a more or lefs convex fhield-like covering, which conftitutes the upper furface of the animal; we call it the upper fhell (carapace, bouclier, &c.); and a nearly flat portion adapted to its concavity below, conftituting the inferior furface of the animal: this is the under fhell (plaftron).

The back fhell is formed by the expanfion of eight ribs or offeous ftaves, which arife from the joints of the vertebræ, and terminate in a border that furrounds the whole fhell: thefe bones are united together by real futures, fituated tranfverfely. Above, and all along the middle part of the fhell, we obferve a row of little offeous plates, almoft fquare, intimately connected together, and to the plates formed by the ribs, by fynarthrofis, and equal in number to the vertebræ. Thefe plates reprefent the rings and fpinous proceffes of the vertebræ. The offeous margin is made up of a great number of pieces, (eleven on each fide, and a fingle one in the middle, before and behind, therefore 24 in the whole,) foldered together, which by their union form an edge or border with three furfaces, *viz.* the fuperior, which belongs to the back fhell; the inferior, which is joined to the breaft-plate by a very thick leather-like fkin; and the internal, which prefents a groove for the reception of the extremities of the ribs. Thefe pieces, which Geoffroy compares to the fternal or cartilaginous portion of our ribs, are wanting in the foft tortoifes, (trionyx, Geoff.); or at leaft remain conftantly cartilaginous or membranous, fo that the middle only of the upper fhell is fuftained by an offeous difk.

The turtles, and the foft tortoifes, are the only genera in which the ribs, confounded in the upper fhell or carapace, are neverthelefs diftinct, both by a prominence very apparent on the infide of the fhell, and by a free unattached portion of their ends projecting beyond the edge of the fhell. But the offeous difk, compofed of articulated pieces, and already mentioned, extends round the ribs in the turtles, receiving their ends, but is wanting in the foft tortoifes. Its folidity is increafed in the former by the great plates which cover it, while it remains flexible in the latter, and is covered only by a fpecies of epidermis.

The offification of the intervals of the ribs, forming the carapace, is perfected gradually, and is not finifhed until long after that of the ribs themfelves: it generally advances from the middle towards the edges. Thus, in a young turtle the ribs will be found feparate from each other, towards their external extremities, for half their length; while in an adult individual of the fame fpecies, the anterior ribs are united throughout, while the intermediate ones are feparated only through about one-fixth of their length.

The carapace is always oval and pointed behind in the turtles; elliptical and gibbous in the land tortoifes; elliptical and flatter in the frefh-water tortoifes. Its furface is rough in the foft tortoifes; elevated into various prominences in the chelydes and the ferpentine, and more or lefs fmooth in the others.

The margin of the upper fhell affumes a different appearance at its anterior part; it is there a fquare piece of bone, convex above, and concave below, which fuftains a fpine for the attachment of mufcles. Its anterior edge has more the form of a crefcent (lunula); there are alfo fome little peculiar pieces above the tail.

The breaft-plate of the tortoife is its fternum; and when deprived of the thick fkin that covers it, exhibits, in fome fpecies, only one folid plate, formed of feveral pieces, united by fynarthrofis: in others, this plate is perforated quite through, and formed of feveral bones, fome of which are fituated in the middle line between the anterior and pofterior part, while others are placed laterally, and faftened together by the help of the former, which fupport them. For further information concerning the offeous fabric of the cheft in thefe reptiles, two memoirs in the 14th vol. of the Annales du Mufeum may be confulted; "Sur les Tortues molles, par Geoffroy St. Hilaire;" "Sur les offemens Foffiles de Tortues, par Cuvier."

In the draco volans the ribs form the fkeleton of the wings, or thofe expanfions of the integuments between the front and back limbs, which are fo called. The five pofterior ribs are elongated and bent backwards for that purpofe. Here progreffive motion is performed by thefe ribs; but they are fuperadded for this purpofe, and make no part of the organs of refpiration. The animal cannot in in truth be ſaid to fly: its lateral membranes act like a parachute, and enable it to take long leaps.

The ribs are uſually articulated to the vertebræ by means of a convex ſurface, which moves upon a ſlightly concave one formed in two of the vertebræ, ſo that the hollow receiving each rib is ſituated between two vertebræ of the back. But in the ſnake tribe the head of the rib has two ſlightly concave ſurfaces, which move upon a convex protuberance belonging to each vertebra; ſo that the rib reſts on a ſingle vertebra. The conſequence of this peculiarity is, that the ribs do not interfere with the motions of the individual vertebræ, and thus that the latter are left free to execute thoſe movements on each other, which take place ſo extenſively in the progreſſion of ſerpents. The articulations of the vertebræ to each other, and to the ribs, are repreſented of the natural ſize from the ſkeleton of a large boa, in the Philoſ. Tranſ. 1812, pt. 1. pl. 6.

We have already ſeen the ribs, inſtead of contributing to the buſineſs of reſpiration, employed for purpoſes of locomotion in the draco volans. They are ſtill more extenſively employed for the ſame purpoſe in the ſerpent tribe, in which they amount ſometimes to 250 pairs, as obſerved by ſir Everard Hume. Theſe bones, in all ſnakes, are continued to the anus, while the lungs ſeldom occupy more than one-half the cavity covered by the ribs. The hind ribs can only be employed for the purpoſe of progreſſive motion, and thus correſpond to the elongated ribs of the lateral membranes in the draco volans.

The ribs of a ſnake may be ſeen to move forwards ſucceſſively when the animal is in motion, like the feet of a caterpillar, and the ends of theſe bones can be diſtinctly felt on the palm of the hand, as the animal paſſes over it.

At the termination of each rib is a ſmall cartilage in ſhape correſponding to the rib, only tapering to the point. Thoſe of the oppoſite ribs have no connection, and when the ribs are drawn outwards by the muſcles, are ſeparated to ſome diſtance, and reſt through their whole length on the inner ſurface of the abdominal ſcuta, to which they are connected by a ſet of ſhort muſcles: they have alſo a connection with thoſe of the neighbouring ribs by a ſet of ſhort ſtraight muſcles.

When the ſnake is going to put itſelf in motion, the ribs of the oppoſite ſides are drawn apart from each other, and the ſmall cartilages at the ends of them are bent upon the upper ſurfaces of the abdominal ſcuta, upon which the ends of the ribs reſt; and as the ribs move in pairs, the ſcutum under each pair is carried along with it. This ſcutum, by its poſterior edge, lays hold of the ground, and becomes a fixed point, from whence to ſet out anew. This motion is beautifully ſeen, when a ſnake is climbing over an angle, to get upon a flat ſurface.

The coluber and boa, having larger abdominal ſcuta, which may be conſidered as hoofs or ſhoes, are the beſt fitted for this kind of progreſſive motion; there is, however, a ſimilar ſtructure of ribs and muſcles in the anguis and amphiſbæna. In the anguis the ribs are proportionally weaker, and as theſe have nothing to correſpond to the ſcuta, this mode of progreſſive motion is probably leſs neceſſary to them. See "Obſervations intended to ſhew that the progreſſive Motion of Snakes is partly performed by means of the Ribs," by ſir Everard Hume, Philoſ. Tranſact. 1812, pt. 1. pag. 183, with figures. We are alſo indebted to ſir Everard Hume, in conjunction with Dr. Ruſſel, for deſcribing more particularly a fact noticed by Blumenbach, (Comp. Anat. p. 117.), *viz.* an adaptation of certain ribs in the cobra de capello (coluber naia, L.) to the accompliſhment of a particular mechaniſm in that animal. This ſerpent is called the hooded ſnake, from a power of expanding the ſkin of the neck, which is effected by the motions of the ribs. In other ſerpents, the ribs, from the firſt vertebra to thoſe of the middle of the trunk, gradually increaſe in length; thence they gradually ſhorten or decline, to near the end of the tail, where they diſappear, or are transformed into ſhort eminences. In the naia, the cervical ribs gradually lengthen to the tenth or eleventh, after which they ſucceſſively ſhorten to the twentieth. Again increaſing in length, they are, at the middle of the trunk, nearly as long as the middle cervical ribs, and then declining as in other ſerpents, diſappear on the tail.

The firſt twenty ribs, inſtead of bending equally with the others towards the belly, go out in a lateral direction, having only a ſlight curvature, and when depreſſed lie at the ſide of the ſpine upon one another. The firſt is ſhorteſt: they lengthen to the tenth, and are again ſhortened to the twentieth; ſo that, when they are extended, they repreſent an oval figure, of which the ſpine is the middle line or long axis. In the extended ſtate of the ribs, the ſkin of the back is brought over them, forming the hood; and in their depreſſed ſtate it recedes. From the rounded form of the hood, the ſkin has the appearance of being inflated; but the moſt careful examination did not diſcover any communication between the trachea or the lungs and the cellular membrane under the ſkin. See "Remarks on the voluntary Expanſion of the Skin of the Neck in the Cobra de Capello," &c. by Pat. Ruſſel, M.D. and Everard Hume, eſq. Philoſ. Tranſ. 1804, pt. 2. pag. 346.

The exiſtence of ribs has been denied in the ſiren lacertina, and proteus anguinus: they have in truth merely very inſignificant rudiments of ribs, that might be eaſily overlooked. Theſe have nothing to do with the reſpiration of the animals, indeed they are too ſmall to anſwer any purpoſe. See the deſcription of theſe animals at the end of the preſent article.

Such rudiments of ribs are ſaid to exiſt in the genus cæcilia, among ſerpents.

Bones of the Shoulder.—In oviparous quadrupeds the glenoid cavity of the ſhoulder is partly compoſed of the ſcapula, and partly *of the clavicle.* The ſcapula, which is elongated, has no ſpine; it contracts and becomes thicker towards the neck. The clavicle is ſimple, ſhort, and flat, and united to the ſternum in the crocodile and lizards. It is broad, and almoſt ſquare, in the iguana and cameleon; in the tupinambis it is oval, and very large and long between the front and back, and has two un-oſſified parts. The frog and toad have two clavicles to each ſhoulder, attached to the two extremities of the ſternum. The ſcapula is bent, and compoſed of two articulated pieces, with the ſuperior one inclined towards the ſpine. The ſame conformation obtains in the Surinam toad. The anterior clavicles appear to correſpond to the os furciforme of birds. The clavicle, the ſternum, and the firſt piece of the ſcapula, are anchyloſed together. The ſalamanders have the ſhoulder formed in a moſt ſingular manner, the ſcapula, clavicle, and ſternum, conſiſt only of a ſingle bone, which receives the head of the humerus. The ſhoulder is almoſt all cartilaginous, but the part anſwering to the ſcapula is more diſtinct than the reſt. It inclines towards the ſpine, where it receives the muſcles by which it is moved. The clavicular part is directed towards the head; that which ſupplies the place of the ſternum turns towards the breaſt, but without uniting with the bone of the oppoſite ſide; the part on the right ſide ſlides over that on the left. This conformation allows a greater dilatation of the breaſt in reſpiration. The tortoiſe

has

has alfo thefe three bones, which unite to form the glenoid cavity, and correfpond with the fcapula, fork, and clavicle. But as their refpective difpofition is very remarkable, it appears neceffary to give a particular defcription of them. One of the bones extends from the bafe of the rudiment of the firft rib, to which it is fixed by a ligament, as high as the humeral cavity, where it is intimately connected with the other two. The fecond bone may be confidered as the continuation of the firft, which it joins at the humeral cavity, of which it forms part. Its other extremity is attached to the breaft-plate, and ftrong ligaments likewife unite the extremity to that of the pofterior bone. Thefe two bones, thus united, are flightly bent outwards, fo as to leave between them and thofe of the oppofite fide, an oval fpace, through which the œfophagus, the trachea, and feveral mufcles, pafs. The firft feems to correfpond to the clavicle, and the fecond to the os furciforme. Finally, the third bone of the fhoulder is fituated below the abdominal and thoracic vifcera, nearer the breaft-plate. It is long, and extends from the humeral cavity, of which it forms the lower part, as far as the abdomen. It feems to fupply the place of the fcapula by the number of mufcles inferted into it, but its fituation is juft the reverfe of that bone. A very ftrong ligament unites this bone to the fecond.

Bone of the Arm.—The humerus of the tortoife has a very remarkable fhape. As in birds it is articulated at once to the fcapula, clavicle, and os furciforme, by a large oval head, the greateft diameter of which lies in the direction of the flatnefs of the bone. A confiderable eminence rifes above this large head, which, by its curvature and its ufes, has fome relation to the olecranon, a procefs which, in this animal, the bone of the fore-arm wants. Below the head there is another eminence, lefs projecting, but more rough, which likewife ferves as a point of infertion to fome mufcles, and fupplies the place of the little tuberofity. The reft of the body of the bone is flattened and narrow towards the middle. In the crocodile, the humerus is round, but a little bent like an S in its whole length. At the extremity that joins the fcapula, it refembles the tibia; its head, inftead of being round, is flat; and its tuberofity, which is fingle, is anteriorly in the form of a ridge, and fomewhat inclined inwards. In the other lizards, and in frogs, the humerus exhibits nothing peculiar. Serpents having no limbs, have confequently no humerus.

Bones of the Fore-arm.—The humerus of the crocodile terminates in two round tubercles. The hollow head of the radius turns upon the external one. Between them the round head of the ulna is fituated, but it has neither olecranon nor figmoid cavity. In the upper part it is the largeft of the two bones, but the fmalleft below. There is nearly the fame conformation in the cameleon, but the bones are more elongated, and the inferior head of the radius is lefs than that of the ulna. In the frog the fingle bone of the fore-arm is articulated by a concave head, with a large round tuberofity on the bafe of the humerus, between its two condyles. On each fide, where the lower part of this bone becomes larger, we obferve a furrow, which is the only veftige of a diftinction into two bones. Troja has pointed out a fingularity in the ftructure of the bone of the fore-arm and of the leg in frogs and toads. Thefe bones confift of a fingle piece, which is folid in the middle, but divided at either extremity into two conical portions, having manifeft medullary cavities. See Memoria fopra la ftruttura fingolare della tibia e del cubito nelle Rane e nei Rofpi, in his Sperienze intorno alla Rigenerazione delle Offa. Nap. 1779, p. 250, t. 7, 8.

The two bones of the fore-arm of falamanders are fituated one above the other. The ulna, which is the loweft, and fomewhat longeft of the two, has no olecranon; but there is a fort of rotula in the tendon of the extenfor mufcles. The ulnar extremity of the humerus is much enlarged. The articulate furface which terminates it is convex, and permits the radius and ulna to turn together in every direction. The two bones of the fore-arm in the turtle are always in a forced ftate of pronation. The radius, which is much longer than the ulna, and fixed to it by a cartilaginous fubftance, is the loweft, and extends even under the carpus. Thefe two bones much refemble each other in the humeral extremity, being formed by a fingle concave furface received upon a correfpondent pulley of the humerus. Their articulation is fuch that it allows them to move together laterally, and a little upward and downward in the action of fwimming.

Bones of the Hand.—The frog, the toad, the falamander, have three ranges in the carpus. The firft confifts of two bones, one radial and one ulnar; the fecond confifts of three bones, the largeft of which bears the rudiment of a thumb with two joints; the third range has likewife three bones. The fecond fingers proceed from the firft of thefe bones; the fourth finger is articulated with the fecond bone; the middle finger articulates with both bones; the little finger joins the third bone. The firft range touches the third inferiorly, becaufe the fecond is cuneiform. There is no bone without the range. In the mud tortoife, the firft range is a fingle bone, which feparates the radius from the ulna: the fecond range confifts of two bones, and a fmall one out of the row, fituated on the ulnar edge: the third range confifts of five bones, one for each bone of the metacarpus. The fea tortoife has three bones in the firft range, the ulnar bone being the longeft. The two anterior bones do not advance much farther. The third range confifts only of three bones for thofe of the metacarpus, and one fmall bone out of the row, fituated upon the radial fide.

In the crocodile, the firft range confifts of two long parallel bones. It has befides two little external bones without the range on the radial fide. The number of the phalanges varies in thefe animals. The crocodile has the hand rounded. It has two phalanges to the thumb, three to the fecond finger, four to the middle and fourth fingers, and only three to the little fingers.

The cameleon has three fingers on one fide, and two on the other, which form, with the three oppofite to them, a kind of forceps. The number of the phalanges is the fame as in the crocodile, with the exception of the little finger, which has four. In the falamander the little finger is obliterated, and the thumb has only two phalanges.

The frog has only one phalanx to the thumb. The two following fingers have only two phalanges. The other two fingers have three.

The hand of the fea tortoife is long, and compreffed in the form of a fin; there are two phalanges to the thumb, three to the three fucceeding toes, and two only to the laft. A fimilar conformation is obfervable in the mud tortoife; with this exception, that its hand is rounded.

Bones of the Pelvis.—In the turtle, that part of the os innominatum which correfponds to the pubis, is the moft confiderable. It proceeds from the cotyloid cavity by a thick portion, which comes forwards and widens into a thin flat lamina, divided into two parts; one is turned towards the middle line, by which the two correfponding bones are united; the other is free, and is directed to the external fide. The portion which correfponds with the ilium is fhort, narrow, and thick; it refts on the fhell, and is joined to the facrum; finally, the portion which is analogous to the

the

the ifchium is turned backward and downward, and forms the real offeous circle of the pelvis. This conformation is fo fingular, that the parts of the pelvis of the turtle, when the whole is viewed out of its natural pofition, may very eafily be miftaken for one another; for the pubis refembles the ilium, the ifchium the pubis, and the ilium the ifchium. There is, befides, another very remarkable peculiarity in the pelvis of tortoifes; the ilium, and confequently the whole mafs of the pelvis with which that bone is united, is moveable on the vertebral column.

In the crocodile, and in the tupinambis, the difpofition of the pelvis has a great refemblance to that of the tortoife. In the crocodile the pubis receives the ventral ribs. In the cameleon and the iguana it is narrow, and the bones of the ifchium form, by this union, a projecting creft. In the frog, and in the Surinam and common toads, the offa ilii are much elongated; the pubis and the ifchium are fhort, and united in a fingle folid piece, the fymphifis of which forms a creft, more or lefs round. In the falamander, the conformation is precifely the fame. The offa ilii are narrow, and almoft cylindrical; and the offa pubis completely united with the ifchium, form only a large bony plate without any hole.

Thigh-Bone.—The femur of oviparous quadrupeds refembles that of other animals; it has, however, a double curvature, more or lefs evident. In front it prefents a convexity towards the tibial extremity, and a concavity near the pelvis. In the tortoife the trochanters are well defined, but they are not to be found in the lizards and frogs. The figure of the femur is in general round, except in the Surinam toad, in which it is very flat.

Bones of the Leg.—Oviparous quadrupeds have the tibia and fibula diftinct and feparated from each other throughout their whole length. Thefe two bones are nearly of the fame magnitude in the tortoifes and lizards. The frog has but one bone, but a furrow feems to indicate the union of the tibia and fibula. In thefe animals the tibia and fibula are, for the moft part, directly articulated to the thigh-bone.

Bones of the Ankle.—The aftragalus is articulated to the tibia, and the os calcis to the fibula in all reptiles. The tarfus of the crocodile has five bones, *viz.* an aftragalus, an os calcis, two cuneiformia, anfwering to the two middle metatarfal bones, and one out of the range, which anfwers to the external metatarfal bone. There are four metatarfal bones. The bone fituated without the range ferves to fupport the little toe in the mud tortoife. In the fea tortoife it is very flat. The os calcis and aftragalus are very fmall. In frogs, the aftragalus and os calcis are very long, and might at firft fight be taken for the tibia and fibula, if they did not form the third joint of the pofterior extremity. There are on the fore part, four little cuneiform, five metatarfal bones, and one in the form of a hook, which is very minute. Thefe are fimilar in the Surinam and common toad.

Bones of the Toes.—The number of the toes varies much in reptiles; as may be feen from the following table.

Number of the phalanges of the toes of reptiles, exclufive of the metatarfal bones, beginning at the pollex, or internal toe.

Crocodile - - -	2, 3, 4, 4.
Lizard - - -	2, 3, 4, 5, 4.
Cameleon - - -	3, 3, 4, 4, 3.
Salamander - -	2, 3, 3, 3.
Sea tortoife - -	2, 3, 3, 4, 2.
Mud tortoife - -	2, 3, 3, 3, 2.
Frog - - -	1, 2, 2, 3, 4, 3.

The faurians prefent us with arrangements in their extremities, not met with in any of the mammalia. We have fpecies poffeffing only fore-limbs, or only hind-limbs; others with four limbs, and one toe only on each; and other unufual combinations in the number of toes on the fore and hind-limbs. Thefe circumftances are noticed in thofe lizards which approach to the form of ferpents, and whofe fmall imperfect limbs feem more like rudiments than complete members, ferving as intermediate links between the faurian and ophidian orders. See Lacépède in the Ann. du Mufeum, ii. p. 351, with figures of a lézard monodactyle, and tetradactyle; and Daudin in his Hift. Nat. des Reptiles, vol. iv. in the hiftory of the genera Seps and Chalcide. We know nothing, however, about the ofteology of thefe—we might almoft fay—ridiculous limbs, they are fo obvioufly inadequate to the purpofe of locomotion.

Of the Mufcles.

Mufcles of the Spine.—There are few fpinal mufcles in frogs. The mufcle which is analogous to the ifchio-coccygeus is large and thin, and occupies all the fpace comprifed between the long bone of the coccyx and the ilia. Its fibres are oblique, and it ferves to draw the coccyx into the direction of the fpine. That which is analogous to the lumbo-coftalis, arifes above the laft by a fort of point attached to the coccyx. It extends quite to the head, into which it is inferted, and detaches fibres in its progrefs to each of the tranfverfe proceffes, which form a kind of interfection upon its furface. The obliquus fuperior arifes from the head at the margin of the foramen magnum, and is inferted into the tranfverfe proceffes of the firft dorfal vertebra. There is only one fmall rectus anterior, it arifes from the bafe of the cranium, below the foramen magnum, and is inferted into the firft of the tranfverfe proceffes. The inter-tranfverfales are like the human. The fpinal mufcles of the falamander much refemble thofe of the frog; thofe of the tail are very fimilar to the mufcles of fifhes. The fpine of the tortoife has no motion except in the parts belonging to the neck and tail. Thofe of the back and loins, which are offified together, have no mufcles. The mufcles of the neck are very different from thofe of man. The motions they produce are thofe of elongation, by which the head is protruded from the fhell; and thofe of retraction, by which it is withdrawn, the neck being bent in the form of a Z. The firft of the mufcles proper to the neck is attached to the under part of the anterior lateral border of the back-fhell, and into the tranfverfe procefs of the firft vertebra; it raifes the neck and draws it back. Another proceeds from the anterior and middle part of the fhell: it is inferted by four flefhy lips, which are feparate throughout a confiderable portion of their extent, into the articular proceffes of the third, fourth, fifth, and fixth vertebræ of the neck. It draws the neck back when the head is much extended, and pufhes it out when it is retracted. A mufcle alfo arifes from the articular proceffes of the third, fourth, and fifth vertebræ of the neck, by three flefhy portions that afterwards unite, and terminate in two tendons; one of which is inferted into the tranverfe procefs of the firft, and the other into the fpinous procefs of the fecond vertebra. This mufcle bends the neck upon itfelf, making it defcribe a curve, which is convex downwards; this motion brings the head under the fhell. A mufcle analogous to the longus colli arifes from the under part of the body of the fecond dorfal vertebra, beneath the fhell; it afcends along the neck, and furnifhes aponeurotic flips to al the tranfverfe proceffes, as as far as the ſecond vertebra, where it is inſerted. This alſo is one of the retractors of the head. There are very diſtinct inter-articulares, which by their action elevate each of the vertebræ, and conſequently extend the neck. The tranſverſo-ſpinalis is ſituated on the poſterior part of the neck: it ariſes from all the ſuperior tranſverſe proceſſes, and is inſerted into all the ſpinous proceſſes as far as the ſixth. Finally, a ſhort muſcle proceeds from the upper part of the firſt dorſal vertebra below the ſhell, and is inſerted into the articular proceſſes of the ſixth and ſeventh cervical vertebræ. This muſcle is peculiar to the tortoiſe, and begins the extenſion of the neck when the head is concealed within the ſhell.

Muſcles of the Ribs, Abdomen, &c.—In the frog, which wants ribs, and the tortoiſe, where they are immoveable, the muſcles which uſually have their inſertions in them, are in thoſe animals extended to other parts. Thus in the tortoiſe, whoſe breaſt-plate occupies the place of the abdominal muſcles, they are inſerted into the pelvis, which they move. With reſpect to thoſe animals, one very remarkable obſervation may, in general, be made. It appears that the very ſingular ſhape of the muſcles and bones depend upon each other. Indeed, as the muſcles are not placed upon the bones, they have not, if we may be allowed the expreſſion, faſhioned them; and the want of motion in the bones, which has given an unnatural figure to the trunk, has alſo given to the muſcles other forms and other uſes. The abdominal muſcles of the frog preſent nothing peculiar, except that the ſkin does not adhere to their ſurfaces, and that inſtead of being inſerted into the ribs, they are faſtened to the ſternum by a ſtrong aponeuroſis. The ſame obſervations may be made with reſpect to the ſalamanders.

We have deſcribed, in the oſteology, the adaptation of the ribs of ſerpents to the purpoſe of progreſſive motion; and now proceed to point out the muſcles by which they are moved forwards or backwards, and connected to the abdominal ſcuta. The ribs are brought forwards by five ſets of muſcles placed on the outſide of the cheſt, and paſſing obliquely from above, downwards, outwards, and backwards. 1. One from the tranſverſe proceſs of each vertebra to the rib behind it. 2. The next ſet ariſes from the ribs, at a ſhort diſtance from the ſpine, paſſes over two ribs, ſending a ſlip to each, and ends in the third. The third ariſes from the poſterior edge of each rib, paſſes over two ribs, and is inſerted into the third rib behind it. The fourth ſet paſſes over one rib and is inſerted in the ſecond. The fifth goes from rib to rib.

The muſcles carrying the ribs backwards are found on the inſide of the cheſt, and ſlant from the ſpine forwards and outwards. A ſtrong ſet ariſes from the anterior ſurface of the vertebra, goes over four ribs, to be inſerted into the fifth about its middle. The ſerrated portions of a ſtrong flat muſcle, forming the muſcular covering of the abdomen, ariſe from this part (the middle of the internal ſurface) of each rib. The right and left muſcles unite in a beautiful middle tendon. Thus it is obvious, that the inferior half of each rib (below the origin of the ſerrated portion juſt deſcribed) is external to the abdominal muſcle, and conſequently free for the purpoſe of progreſſive motion.

The ends of the ribs are connected to the abdominal ſcuta by a ſet of ſhort muſcles: they are alſo connected together by ſhort and ſtraight muſcles. Another ſet goes from the heads of the ribs obliquely backwards to be fixed in the ſkin at the edge of each ſcutum. See ſir E. Hume's paper quoted in the oſteology; and particularly plates 4 and 5 from Mr. Clift's drawings, in which the parts are repreſented.

There is a complicated muſcular apparatus for extending and retracting the ribs, and carrying the ſkin forwards and backwards in the cobra de capello. The ribs are raiſed or carried forwards by four ſets of muſcles, all ariſing from and inſerted in theſe bones, and directed obliquely from above, downwards and outwards.

The ſkin of the back is brought forwards on the neck by a large ſet of very long muſcles, ariſing ſucceſſively from each of the firſt twenty ribs, by a tendon, which ſoon becomes fleſhy. The longeſt is about two inches. They go backwards to be inſerted into the ſkin, which they can bring forwards to a great extent when the ribs have been firſt extended.

The muſcles which carry the ribs back again lie on the inſide of the cheſt under the ſpine. One ſet goes from the vertebræ of the neck to the lower edges of the ribs: but they paſs obliquely upwards and outwards over three ribs, to be inſerted into the fourth, thus acquiring a length of fibre, by which the range of motion produced is much increaſed. The ſecond ſet goes from the ends of the ribs forwards to the ſkin, which they will draw back. The third ſet from the root of one ſcutum to the ſcutum immediately above it, ſo as to bring it down upon the other. Sir E. Hume's and Dr. Ruſſel's paper, and particularly the engravings from Mr. Clift's drawings. Phil. Tranſ. 1804, pt. 2.

Muſcles of the Head.—The muſcles of the head of the tortoiſe cannot be deſcribed under names ſimilar to thoſe of mammiferous animals and birds, becauſe the ſhell affords inſertion to the greater number of them. We will, therefore, only diſtinguiſh them by the points of attachment. Thus, on viewing the back part of the neck, we remark, 1ſt, at the anterior part of the back-ſhell, near the angle of the lunula, a broad muſcle, which extends to the lateral and poſterior parts of the head, into which it is inſerted. It pulls the head backward. 2. Beneath, and from the middle of the anterior lunula of the back-ſhell, there ariſes another muſcle, which is thin and round, and which, in ſeparating from that of the oppoſite ſide, forms an angle like the letter V: it is inſerted on the outſide of the preceding muſcle, and has the ſame uſe. 3. A muſcle analogous to the ſplenius capitis riſes from the ſpinous proceſſes of the fourth and fifth cervical vertebræ, by diſtinct ſlips, and is inſerted into the occipital arch. Its uſe is to raiſe the head. 4. A muſcle analogous to the rectus major anticus riſes from the inferior tubercles of the four vertebræ next to the atlas, and is inſerted, fleſhy and thick, into the depreſſion of the cuneiform proceſs below the condyle. 5. The trachelo-maſtoideus riſes from the inferior tubercles of the ſecond and third cervical vertebræ, by two thin aponeurotic tendons; it is inſerted, by a very thick and entirely fleſhy portion, into the protuberance that anſwers to the maſtoid proceſs. Its uſe is to bend the head laterally. 6. Laſtly, at the ſuperior part of the cervical ſpine there is a ſhort muſcle, which proceeds from the inferior part of the foramen, formed by the temporal foſſa, and is inſerted into the ſpinous proceſſes of the firſt, ſecond, and third vertebræ of the neck. On viewing the neck in front, we obſerve the muſcle analogous to the ſterno-cleido-maſtoideus attached to the ſtrong aponeuroſes that ſurround the humerus at its articulation with the ſcapula. The lower part of it, for one-third of its length, can only be ſeen, the remainder being concealed by a muſcle compoſed of tranſverſe fibres, which ſupplies the place of the mylo-hyoideus, and platiſma-myoides. It is inſerted into a proceſs correſponding to the maſtoid. Its uſe is to draw

draw the head inwardly, and to produce a ſmall elevation of the ſhoulders. The longus capitis ariſes from the third vertebra of the back, and is inſerted by a ſlender tendon into the cuneiform proceſs of the occiput. The frogs have very few of the muſcles of the head: moſt of thoſe which are inſerted in it are employed in moving the ſuperior extremities, or are proper to the vertebral column. The muſcle analogous to the obliquus ſuperior ariſes from the firſt tranſverſe proceſſes of the ſpine, and is inſerted into the ſuperior part of the occiput: its direction is oblique from without inwards. That which is analogous to the rectus capitis anticus minor, ariſes from the tranſverſe proceſs of the firſt vertebra, and is inſerted into the baſis of the cranium below the foramen magnum. Theſe are the only two muſcles proper to the head in frogs: they are ſimilar in the land ſalamander.

Muſcles of the Shoulders.—In the frog (which has no ribs) the ſerratus major has an extraordinary ſhape, which appears to be occaſioned in part by the want of the cervical vertebræ: it forms three diſtinct muſcles. The firſt ariſes from the occiput, near to the foramen magnum. It divides into two bellies, which are inſerted into the ſuperior ſpinal angle of the ſcapula; one on the internal, and the other on the external ſide. The ſecond proceeds from the ſecond tranſverſe proceſs, and paſſes under the dorſal portion of the ſcapula, towards its ſpinal edge. The third proceeds from the third tranſverſe proceſs, and paſſes underneath the preceding, keeping ſtill nearer to the edge. There is beſides another muſcle proper to the ſcapula, ſituated upon its internal ſurface, between the two conſtituent parts, which make it appear broken. It appears to draw theſe two parts cloſer together, and by its contraction renders the angle they form with each other more acute. There is no muſcle analogous to the pectoralis minor. The place of the levator, or angularis ſcapulæ, is ſupplied by a very conſiderable muſcle which riſes from the baſe of the occiput; it becomes perceptibly ſmaller as it approaches the ſhoulders, and is inſerted into the poſterior edge of the cartilaginous part of the ſcapula. The omo-hyoideus is long and thin; it comes from the great inferior horn of the os hyoides, and is inſerted under the neck of the ſcapula. The trapezius is wanting. The muſcle analogous to the rhomboides is very thin. It ariſes from the dorſal proceſſes, and is inſerted into the ſpinal edge of the ſcapula. There is no ſubclavius muſcle. The ſterno-maſtoideus has only one belly, which extends obliquely from the poſterior part of the head, behind the ears, to the neck of the oſſeous part of the ſcapula. Its action is evidently that of pulling the ſhoulder towards the head, and raiſing it up. We ſhall deſcribe the muſcles of the tortoiſe ſeparately, as they differ conſiderably from thoſe of other red-blooded animals. They are only three in number. One of them, though very unlike the trapezius, is ſimilar in its uſe; it riſes from the lower ſurface of the back-ſhell among the ribs, from the ſecond to the fifth. It is very thin, and paſſes to the external margin of the third bone of the ſhoulder, which ſeems to correſpond with the ſcapula. A muſcle analogous to the levator ſcapulæ, is inſerted into the curve formed by the joint of the two firſt bones of the ſhoulder. It ariſes by ſeven fleſhy heads from the tranſverſe proceſſes of the ſeven vertebræ of the neck. Another little long muſcle ariſes from the inner ſurface of the back-ſhell near the ſternal extremity of the firſt rib, and is inſerted into the dorſal extremity of the firſt bone of the ſhoulder. It is perhaps analogous to the coſto-clavius.

Muſcles of the Arm.—The pectoralis major of the frog is compoſed of two portions, placed one above the other. They produce two tendons which are inſerted on each ſide of the humeral groove. The latiſſimus dorſi ariſes from the inferior part of the back, where it is thin. It becomes thicker, and is attached to the broad part of the ſcapula, which it entirely covers. It is inſerted, by a ſtrong tendon, into the internal ſurface of the humerus, above one-third of its length from its ſuperior end. In the frog there is neither the ſupra nor the infra-ſpinatus. The ſubſcapularis or coraco-brachalis, (for the muſcle of which we now ſpeak ſupplies the place of both,) ariſes from the internal ſurface of the ſcapula, at its junction with the clavicle, and is inſerted into the interior part of the humerus about one-third from the head. The deltoid is formed of three portions. The firſt, which is the longeſt, and very ſlender, proceeds from the anterior part of the ſternum. The ſecond ariſes from the union of the clavicle with the ſcapula, at the internal ſurface, runs over the bone above the joint, then ſends a thin tendon to the firſt in its paſſage, and is partly inſerted in the linea aſpera, and partly in the inferior portion of the humerus. The third is diſtinct; it riſes partly from both the ſcapula and clavicle, and is inſerted into the ſcapular extremity of the humerus. The teres major and teres minor are wanting. Beſides theſe muſcles, in which we diſcover an analogy to thoſe of mammiferous animals, there is one which ariſes from the ſecond tranſverſe branch of the ſternum, and is inſerted into the inner edge of the groove of the humerus by a broad tendon. It may be regarded as an aſſiſtant to the pectoralis major. This conformation appears to prevail in the ſalamander.

If the tortoiſe has fewer muſcles proper to the ſhoulder than common, it has an extraordinary number inſerted into the humerus. That which correſponds to the pectoralis major is compoſed of five portions. Two are ſuperficial; one ariſes from the edge of the anterior part of the breaſt-plate, and proceeds to its inſertion in the leſſer tubercle of the humerus. The other is much more extenſive: it riſes from a great part of the internal ſurface of the breaſt-plate, and is alſo inſerted by a flat tendon in the leſſer tubercle of the humerus: but it is prolonged by a fan-like aponeuroſis, which extends over the inferior ſurface of the arm, and even of the fore-arm. One of the three deeper portions of the pectoralis major ariſes from the greater part of the ſecond bone of the ſhoulder, and is inſerted into the humerus, below its ſcapular articulation; another ariſes from the expanſion of the interoſſeous ligament, which unites the ſecond bone of the ſhoulder to the third, and proceeds to join its tendon intimately with that of the preceding portion. Laſtly, the third, which is the moſt deep-ſeated of all, ariſes from the ſuperior ſurface of the third bone of the ſhoulder, or that which is next the back-ſhell. Its tendon is conjoined with thoſe of the preceding. The muſcle analogous to the deltoides is alſo compoſed of two portions; one ariſes from a ridge on the anterior part of the breaſt-plate; the other, which is its acceſſory, is placed more deeply, and united to its correſponding muſcle. They are inſerted by one common tendon into the leſſer tubercle of the humerus, which they draw towards the neck in the action of ſwimming. There is another muſcle much deeper ſeated, which ſeems likewiſe an aſſiſtant to the deltoides. It riſes from the dorſal extremity, and all the internal edge of that bone of the ſhoulder which correſponds with the clavicle, and proceeds to be inſerted into the humerus below the leſſer tuberoſity. On the internal ſurface of the humerus, we find a muſcle riſing from the looſe extremity of the ſternal face of the third bone of the ſhoulder: it is inſerted in the humerus, about one-third from its lower end, by a thin tendon. It bears ſome relation to the ſterno-radialis of the frog, and performs the ſame office.

The

The levator brachii is a very thick muſcle, which ariſes from the third bone of the ſhoulder, the exterior edge of which it ſurrounds, and is inſerted into the proceſs of the humerus reſembling the olecranon, which it pulls upward and outward. A muſcle analogous to the teres major ariſes from the neck of the third bone of the ſhoulder, externally, and is inſerted into the humerus between the two tuberoſities. It pulls the humerus backward. Another muſcle, which ſeems a ſubſtitute for the latiſſimus dorſi, riſes from the interior part of the back-ſhell, to which it is attached obliquely, to the interval between the two firſt ribs. It is inſerted into the body of the humerus behind the greater tubercle, by a flat tendon. It pulls the humerus towards the upper ſhell, when the animal ſtands upon all its four feet. A muſcle, the uſe of which ſeems the ſame as that of the levator brachii, riſes from the whole internal ſurface of that bone of the ſhoulder which anſwers to the clavicle, and is inſerted into the whole length of the olecraniform proceſs, or great tuberoſity of the humerus. It is very fleſhy, and appears to be formed of two portions. Finally, the muſcle analogous to the ſcapulo-radialis, or biceps flexor cubiti, ariſes from the anterior border of the humeral cavity, and is inſerted into the external and ſuperior ſurfaces of the humerus by a ſmall tendon, which reaches as far as the baſe of the radius. It extends the member, and brings it toward the head.

Muſcles of the Fore-arm.—The frog has, properly ſpeaking, no biceps; its place is ſupplied by another, and much ſtronger muſcle, ſituated on the breaſt, under the pectoralis major, with which it has the ſame inſertions. At the articulation of the humerus it ſends out a ſtrong tendon, which paſſes along the groove of the humerus, and through a tendinous ring, formed by the two parts of the pectoralis major, under the deltoides. It is inſerted into the humeral extremity of the radius, and may be named ſterno-radialis. There is no brachialis internus. The triceps is compoſed of three parts, nearly as in man, but they are proportionally larger. There is but one ſupinator, which ariſes from the external condyle, and is inſerted into the carpus. There is alſo but one pronator, which riſes from the internal condyle, and is inſerted into the carpus. In the turtle, theſe muſcles are almoſt entirely aponeurotic, and produce but very little motion, the place of the member being ſupplied by a fin, as in the cetacea. In general, the muſcles of the humerus produce the motions of the fore-arm.

Muſcles of the Hand and Fingers.—In the ſea tortoiſes, which have the carpus compreſſed and fitted for ſwimming, the muſcles are only ſimple bands of aponeurotic fibres, which ſtrengthen the ſeveral articulations. The muſcles of the hand of the frog and ſalamander are very ſimilar to thoſe of man. Thoſe of the thumb are wanting, except the extenſor, which comes from the external condyle, and is inſerted into the laſt phalanges. The other muſcles vary very little.

Muſcles of the Pelvis.—In the tortoiſe, the muſcle analogous to the quadratus lumborum expands under the back-ſhell, between the laſt anterior ribs; it ariſes from the ilium, towards the articulation of that bone with the os ſacrum, which in this animal is moveable. This mobility of the pelvis is aſſiſted by a muſcle analogous to the rectus abdominis, which, as we have obſerved, inſtead of extending under the belly, is attached under the poſterior extremity of the breaſt-plate by two fleſhy portions, the one anterior, the other poſterior, which are both inſerted in the anterior margin of the external branch of the pubis. There is no pſoas parvus in frogs. The quadratus lumborum extends from the long tranſverſe proceſs of the third vertebra, to the origin of the long bone of the pelvis, which is analogous to the ilium. It is inſerted in this bone, which it raiſes towards the head; their ilium being moveable, like that of the tortoiſe.

Muſcles of the Thigh.—In the frog there is only one glutæus, which is in the place of the medius. It ariſes from the elongation which ſupplies the place of the os ilium, and is inſerted below the head of the femur. The pyriformis comes ſtraight from the point of the coccyx, and is inſerted about one-third from the top of the os femoris. The gemini and the obturator internus are wanting. The quadratus femoris is long. It ariſes from the poſterior ſymphiſis of the iſchium, and is inſerted into the inner ſide of the thigh-bone, about one-third from the head. They have neither the pſoas magnus nor parvus. The iliacus is proportionally elongated. The pectineus deſcends to the middle of the thigh-bone. The three adductors have the ſame origins and inſertions as in man. The obturator externus is to be found, though there is no foramen ovale. It ariſes from the ſymphiſis pubis, and its fibres are attached to the capſular ligament. In the tortoiſe, the muſcles of the thigh produce motions proper to ſwimming; that is to ſay, the abduction, the adduction, depreſſion, and elevation of the thigh. The muſcle analogous to the adductor longus ariſes from the ſymphiſis pubis, and is inſerted into the internal part of the thigh-bone, about one-third from its tibial extremity. Another muſcle, which cannot be eaſily compared to any in man, ariſes from the interior of the ſacrum, and is inſerted into the little trochanters. It is another adductor femoris. A muſcle, compoſed of different radiated faſciculi, ariſes from the broad inferior ſurface of the os pubis, and forms a thick tendon inſerted into the little trochanter. It occupies the place, and anſwers the purpoſes, of the pſoas and iliacus. That which is analogous to the adductor brevis ariſes from the ſymphiſis of the bones of the iſchium, and the interoſſeous ligament of the pubis. It is inſerted into the os femoris, below the little trochanter. The muſcle anſwering to the glutæus maximus ariſes from the ſpine, oppoſite to the laſt rib, and is inſerted into the thigh-bone, below the great trochanter. The muſcles analogous to the glutæus medius and minimus can hardly be diſtinguiſhed from each other. They riſe from the internal ſurface of the os pubis, and are inſerted into the great trochanter. That which reſembles the obturator internus ariſes from the internal ſurface of the ilium, and the ſuperior edge of the cotyloid cavity, and is inſerted into the great trochanter.

Muſcles of the Leg.—The frog has the thighs round, like thoſe of a man, and the muſcles of the leg are very conſpicuous. The triceps femoris is formed only of two very diſtinct portions. The vaſtus externus and cruralis are manifeſtly but one. There is no rectus anterior. The biceps flexor cruris has only one belly. It ariſes from the poſterior and internal part of the ilium, and is inſerted into the exterior and anterior ſurface of the tibia, for there is no fibula. The ſemi-membranoſus is like the human; but the ſemi-tendinoſus is compoſed of two bellies, one of which riſes from the ſymphiſis pubis, and the other from that of the iſchium. The ſartorius is ſituated exactly in the front of the thigh, without any obliquity. There is nothing remarkable in the gracilis. There is no diſtinct poplitæus. Some differences occur in the muſcles of the leg of the tortoiſe. Theſe have a relation to the faculty of ſwimming, for which its extremities are fitted. The muſcle which takes the place of the ſemi-membranoſus ariſes from the interoſſeous ligament of the pelvis, and proceeds to form a ſtrong aponeuroſis at the inferior part of the leg. That which correſponds to the ſemi-tendinoſus ariſes alſo from the interoſſeous ligament;

ment; it paſſes under the ham, and is inſerted into the tibia, which it bends. That which is analogous to the ſartorius ariſes from the os pubis, near the interoſſeous ligament, and paſſes over the knee, to be inſerted into the tibia, which it extends. A muſcle compoſed of two fleſhy portions, both of which ariſe from the lateral parts of the ſacrum, is inſerted below the head of the tibia, and bends the leg. In its action, it much reſembles the biceps, from which, however, it differs with reſpect to its attachments. Another muſcle, reſembling the faſcia lata, and very thin in its fleſhy part, ariſes from the ſides of the coccyx. It paſſes under the ſkin of the ſin, to its inſertion, almoſt oppoſite to the heel. It bends the leg upon the thigh, and extends the foot upon the leg. The muſcle analogous to the biceps ariſes from the ſacrum and ilium. It goes to the external ſurface of the leg, where it is inſerted into the fibula. The extenſor of the leg preſents nothing particular. The muſcle analogous to the rectus anterior ariſes from the internal ſurface of the pubis, and joins the common tendons of the extenſors.

Muſcles of the Ankle.—In the frog, the gaſtrocnemius has only one belly; it has, however, a ſmall tendon, by which it is inſerted into the outward ſide of the head of the tibia. Its tendon runs under the heel, and there ſliding over a ſeſamoid bone, expands itſelf under the foot, to form the plantar faſcia. There is neither ſoleus nor plantaris. The tibialis anticus riſes by a ſtrong tendon from the lower part of the os femoris. About the middle of the tibia it divides into two bellies, one internal, the other external. The tendon of the firſt is inſerted into the tibial baſe of the long bone of the tarſus, and that of the ſecond into the ſame bone, a little more outwardly. An aſſiſtant to this muſcle ariſes from the middle and anterior part of the tibia, and proceeds to the internal ſide of the baſe of the long bone of the tarſus. The tibialis poſticus reſembles the human, but it is only inſerted into one bone of the tarſus, *viz.* that which is long, and ſituated at the inner ſide. There is but one muſcle, to which the term peroneus can apply. It ariſes by a ſlender tendon, from the external condyle of the thigh, and is inſerted into the baſe of the tibia, on the outſide, by two tendinous portions, one of which extends to the bone of the tarſus. It extends the leg with reſpect to the thigh, or, more properly, the thigh with reſpect to the leg. Beſides theſe muſcles, which extend from the leg to the foot, there is another which ariſes from the metatarſal extremity of the tibia, at its internal edge, paſſes between the two bellies of the tibialis anticus, and proceeds very obliquely to its inſertion, at the digital extremity of the long bone of the tarſus, on its inner ſide. In the ſea tortoiſe, the muſcles of the feet are ſupplied by aponeurotic fibres, ſomewhat fleſhy, which ſerve only to ſtrengthen the articulations, and keep the fins properly extended.

Muſcles of the Toes.—There is no extenſor longus digitorum in the frog; neither is there any flexor proprius pollicis. The extenſor brevis digitorum is very diſtinct, it ariſes from the whole length of the long external bone of the tarſus, and extends obliquely to all the four toes, the laſt excepted. It is inſerted into the laſt phalanges. There are ſuperior and inferior interoſſeous muſcles, which are very apparent, to the number of ten. Their direction is very oblique. The flexor communis digitorum is ſituated under the long bone of the tarſus, on the inner ſide, and is covered by the aponeuroſis of the gaſtrocnemius. When it reaches the little bones of the tarſus it divides into five tendons, which receive, at their inner ſide, aſſiſtant fleſhy fibres, apparently proceeding from a muſcle ſituated below the long bone of the tarſus, on the inner ſide. It may perhaps repreſent the flexor longus. In the ſea tortoiſe all theſe muſcles have their places ſupplied by bundles of aponeurotic fibres.

On the Support of the Body, and its Motions in Progreſſion.—*Standing* is an attitude common to all animals, but the circumſtances attending it differ very conſiderably. In moſt of the oviparous quadrupeds, the knees and elbows are directed outwards as they ſtand, and even during their various progreſſive motions. The poſterior members, articulated more in proportion at the ſides of the body, are ſo bent, that the belly deſcends to the ground, and moves along it.

Turtles reſt on their plaſtron, and on their four flattened, elongated, and fin-like members. They may be compared to ſeals in their mode of executing movements. They employ their members, either in ſwimming, or in walking on the ſea-ſhore, or in digging holes in the ſand to receive their eggs.

In tortoiſes, ſtanding is nearly the ſame as moſt in other oviparous quadrupeds; and the direction of their body is horizontal. Batracians, and frogs in particular, generally have their body, when at reſt, in an oblique elevation; the arms ſuſtaining the front part, while the back remains on the ground. The formation of the poſterior limbs does not render them adapted to raiſe the body in a vertical direction, but merely to puſh it forwards.

Serpents, in a ſtate of repoſe, coil up their body in ſeveral circles, either riſing one above the other, or arranged one within the other; and the head is elevated above this coil. Thoſe which inhabit trees are twiſted round the branches. The chalcides and biped lizards may be compared to ſerpents when at reſt, for they are coiled up, and their limbs ſerve merely to prevent the body from rolling.

Walking exhibits different modifications, according to the number and form of the limbs, and the relative ſize of the fore and hind-feet. Where they are of equal length, the animals move with great velocity: hence the names of certain ſpecies, as lacerta agilis and velox. When, however, the limbs are too ſmall and weak for the body, the movements are ſlower, as in the crocodile, the chalcides, and the toad.

The feet of the cameleon, and its prehenſile tail, make it a better climber than moſt reptiles.

The limbs being all of nearly equal length in the ſcinks, they cannot leap well: while the iguanas and tupinambes exhibit conſiderable agility. The frogs are the great jumpers, from the great length and ſtrength of the hind limbs. But they can hardly walk; moving the front legs only with facility, and being obliged almoſt to drag the hind ones after them.

Serpents can leap or project their bodies by the ſudden extenſion of ſeveral articulations: they form ſeveral curves with their body, and then ſuddenly ſtraighten them, either in whole or in part, according to the leap which they may wiſh to make.

Creeping, properly ſo called, belongs only to ſerpents, and conſiſts of a projection of the body backwards or forwards, produced by the alternate motion of one or ſeveral of the lower parts againſt the ground. The following modifications are exhibited in different inſtances. 1. Creeping by vertical undulations. 2. By horizontal undulations. 3. By two or three undulations of the poſterior third part of the body, while the two anterior thirds are elevated vertically. 4. A ſliding kind of crawling, by ſmall undulations formed by the alternate approximation and ſeparation of rows of ſcales placed tranſverſely under the body. 5. The

5. The fame kind of motion, produced by the alternate formation and difappearance of folds in the fkin of the fides. 6. Without any undulation, merely by the alternate approximation and feparation of rings of the body.

The repulfive motions, by which reptiles move their bodies forwards in water, are nearly the fame as they employ in jumping; but they muft be much quicker. To rife in the water, they muft ftrike back the water below and behind them, and diminifh the breadth of their body, as much as poffible, by carrying their fwimming organs backwards after each ftroke. Thus we fee the frog, after ftriking, extend its long hind legs, fo as to offer no refiftance to the paffage of the body through the liquid. The act of fwimming offers the following modifications. 1. External fwimming (on the furface of the water, breathing air) by vertical undulations, without fwimming organs. The ferpents. 2. The fame by lateral undulations, affifted by the feet. Iguanas, lizards, &c. 3. Swimming under the furface, breathing externally; by four palmated feet, and without tail. Hyla palmata (Rana maxima, Linn.) 4. The fame with four legs and no tail. Frogs properly fo called. 5. The fame with four feet, an elongated body, and depreffed tail. Crocodiles, falamanders. 6. The fame by means of four fin-like fcaly members, and no tail. 7. Swimming under water, breathing by means of branchiæ.

The dragons are the only reptiles capable of flying. Their flight is nearly the fame with that of the polatouche, or flying fquirrel. Daudin, Hift. Nat. des Rept. t. 1. p. 256.

The Brain.—The brain of reptiles does not fill more than one-half of their very fmall cranium; hence its relative fize to that of the body is very inconfiderable. Its proportion to the body is faid to be, in the tortoife $\frac{1}{2240}$, in the turtle $\frac{1}{5688}$, in the coluber natrix $\frac{1}{792}$, in the frog $\frac{1}{172}$. Blumenbach juftly obferves, that anatomifts have hitherto beftowed but little labour on the brains of the amphibia. The dura mater forms no proceffes in this order; the interval between it and the pia mater is filled with fluid; the brain is fmall and fimple, and confifts of five roundifh eminences. Of thefe, the fingle one, placed at the front of the medulla fpinalis, is clearly the cerebellum, as in all animals which have a nervous fyftem. Whether the four others are to be regarded as the two hemifpheres, and the thalami nervorum opticorum, is more doubtful. According to Blumenbach, the cerebellum does not exhibit the arbor vitæ.

All the parts of the brain of reptiles are fmooth, and without circumvolutions. The optic thalami are fituated behind the hemifpheres, but are not covered by them. They contain each, as in birds, a cavity which communicates with the third ventricle. At the extremities of this ventricle, we obferve the anterior and pofterior commiffure, but there is no foft commiffure, nor tubercula quadrigemina.

In the tortoife the hemifpheres form an oval. Their anterior part is feparated from the pofterior by a fulcus, and reprefents a kind of bulb, which ferves as a root to the olfactory nerves. The fize of this bulb is about equal to one-third of the hemifphere. The interior of the hemifphere is, as ufual, excavated by a ventricle, and contains a fubftance analogous to the corpus ftriatum, and which pretty much refembles in its form that of birds.

The optic thalami are not larger than the bulbs of the olfactory nerves. Their form is nearly round. They extend downward and forward, under the hemifpheres, to produce the optic nerve. The valve of the cerebrum is fituated between them and the cerebellum. No tubercle is either placed above it or before it, and it gives origin, as ufual, to the fourth pair of nerves.

Before the optic thalami, and under the pofterior part of the hemifpheres, there is a tubercle which correfponds to that we have remarked in birds.

The cerebellum is nearly hemifpherical. The fourth ventricle penetrates a confiderable way into its fubftance.

In the frog the hemifpheres are longer and narrower. The optic thalami are larger in proportion to the hemifpheres. Their ventricle is very diftinct. It is the contrary in falamanders, which have the optic thalami very fmall, and the hemifpheres almoft cylindrical.

The cerebellum of thefe two kinds of reptiles is flat, triangular, and lies pofteriorly on the medulla oblongata.

In the ferpents the two hemifpheres form together a mafs which is broader than long. The optic thalami are almoft round, and one-half lefs than the hemifpheres, behind which they are fituated. The olfactory nerve has no apparent bulb. The cerebellum is exceedingly fmall, flat, and in the form of a portion of a circle.

In all thefe animals the inferior furface of the brain is nearly fmooth. The optic thalami make no projection downward, and the pons Varolii does not exift.

Cuvier affigns, as the diftinguifhing character of the brain in reptiles, the pofition of the optic thalami behind the hemifpheres. And he ftates the following as the points in which reptiles, fifhes, and birds, differ from the mammalia. The want of corpus callofum, fornix, and their dependencies. Some tubercles, more or fewer, between the corpora ftriata and the optic thalami. The thalami containing ventricles, and being diftinct from the hemifpheres. The abfence of any tubercle between the thalami and the cerebellum, as well as the abfence of the pons Varolii. Reptiles and fifhes are diftinguifhed from the mammalia and birds by the want of the arbor vitæ.

The brain of the tortoife has been delineated by Caldefi, offervazioni intorno alle Tartarughe, tab. 2. fig. 5: that of the frog by Ludwig, de cinerea cerebri fubftantia; by Vicq d'Azyr in the Mem. d'Acad. des Sciences, 1783; and by Ebel, in his Obfervat. Neurol. ex Anat. Compar.; and that of the viper, by Vicq d'Azyr.

Origins of the Nerves.—The olfactory nerves arife, as in birds, from the anterior extremity of the hemifpheres. The optic nerves feem to derive their origin from a common eminence, fituated under the middle of the hemifphere. The other nerves exhibit no particularities as to their origin.

Diftribution of the Nerves.—The *olfactory* nerve proceeds to the noftrils in this clafs nearly in the fame manner as in birds; but it is longer. The canal which receives it is partly offeous and partly cartilaginous. The two canals have only one common aperture within the cranium. The olfactory nerves of reptiles are generally much more folid than thofe of the preceding claffes.

The two *optic* nerves are joined together, as in the mammalia. There is nothing worthy of remark about the third, fourth, and fixth pairs.

Reptiles have the three branches of the *fifth pair*. In the fea tortoifes the ophthalmic paffes, fome way, in the dura mater before it enters the orbit. It tranfmits filaments to the mufcles of the globe of the eye, and particularly to the two lachrymal glands. The fuperior maxillary branch is the largeft of the three. It is united to the inferior branch at its origin, but when it reaches the interior of the orbit, it feparates from it to take another direction. It paffes along the floor of the orbit, defcribing a very marked curvature, the convexity of which is external. A very great number of filaments proceed from the concave or internal fide,

fide, which are loft in the lachrymal gland. The trunk is afterwards divided into two branches :—one internal, which correfponds to the fpheno-palatine and fub-orbitar nerve. It furnifhes filaments to the palate and to the nofe; and when arrived at the anterior part of the orbit, it proceeds outwardly and fpreads upon the face. The other branch of the principal trunk is external; it paffes alfo upon the floor of the orbit, to which it gives many filaments, and at length iffuing from the inferior part of the orbit, it expands upon the face, anaftomofing with the other facial nerves.

The inferior maxillary branch proceeds almoft vertically downward to the pofterior pa t of the orbit, before the petrous and articular procefs of the os temporum. In its courfe towards the lower jaw, it paffes between the temporal and pterygoid mufcles, to which it fends feveral filaments. Having arrived at the lower jaw, before the articular furface, it enters the oblong aperture, and divides in the fubftance of the bone. It forms feveral branches on the inner part of the jaw, which are loft in the mufcles of the tongue, and on the outfide fome others which ramify under the fkin.

The *facial* nerve exifts in birds and reptiles, but its fize is fmall, becaufe thefe animals have no lips, and becaufe their mouth, as well as a great part of their face, is covered with a horny or fcaly fubftance, in confequence of which thefe parts have but little motion or fenfibility. We find, however, fome of the branches: they are not indeed eafily followed in diffection, but their trunk always exifts.

The *auditory* is united to the facial nerve as in the mammalia, and paffes into a meatus auditorius, whence its branches go into the ear. They will be defcribed in the account of the ear.

We have nothing remarkable to ftate refpecting the *par vagum* or eighth pair of nerves in reptiles. We obferve evidently that it is diftributed to the lungs, the heart, the œfophagus, and ftomach, and that it forms plexufes on thefe organs, in the fame manner as the great fympathetic nerve produces them round all the arteries of the trunk. On leaving the cranium, the par vagum forms decuffations with the lingual and gloffo-pharyngeal nerves; they afterwards feparate from each other: the gloffo-pharyngeus is pofterior, the par vagum in the middle, and the lingual anterior. The par vagum does not always come out of the cranium by a fingle hole; it is formed of two or three filaments, which afterwards rejoin, upon receiving a communicating filament from the gloffo-pharyngeus, and one farther down from the lingual; the nerve then augments fomewhat in diameter, and defcends into the breaft.

We have nothing to remark concerning the gloffo-pharyngeal and hypogloffal nerves.

Tortoifes have eight pair of *cervical nerves*, which are diftributed nearly in the fame manner as in mammalia. The three laft pairs join in forming the brachial plexus. The green lizard has four pair of cervical nerves, but only the two laft enter into the compofition of the plexus. In falamanders and frogs the cervical nerves cannot be properly diftinguifhed from the dorfal, as the animals have no ribs. A pair comes out between the firft and fecond vertebræ, which is fent to the mufcles of the inferior part of the neck, and under the fkin that covers them. Thefe nerves alfo afford fome filaments to the fhoulder. From this diftribution they may be regarded as real cervical nerves. In frogs only two pairs enter into the compofition of the plexus. In the falamander there are diftinctly four.

We refer to the tables which indicate the number of the vertebræ in reptiles, in order to fhew the number of nerves which iffue from their foramina. The diftribution of thefe nerves is the fame as in other animals, and to point it out would be only repeating what we have already defcribed in man.

Nerves of the front Limbs.—In the tortoife the three laft pairs of cervical nerves, and the firft of the dorfal, proceed to the thoracic member, where they form a plexus in the following manner: the fifth cervical paffes behind the other four pairs, croffes them in their courfe, and unites with them in its paffage. It then turns round the fcapula, which in this animal is articulated with the firft dorfal vertebra. We fhall return to the defcription of this nerve. The fixth cervical pair proceeds directly along the fcapula on its internal furface: it is croffed pofteriorly by the fifth, and towards the lower third of the fcapula receives the feventh cervical pair. The feventh is flender, croffed by the fifth and the firft dorfal pair, and united with the fixth, in the manner we have pointed out. The firft dorfal pair partly joins the feventh cervical, almoft at the point where it comes out of the vertebral canal; it is then fent to the mufcles of the fhoulder.

We fhall now purfue each of the cords we have mentioned to their termination.

The large nerve produced by the fifth cervical pair, having arrived behind and near the true articulation of the fcapula with the fpine, divides into three branches; one, which is but a filament, appears to be diftributed to the articular capfule; a fecond, which is very flat, and from the fides of which a vaft number of leffer branches extend to the mufcles of the fkin, appears to take the place of the mufculo-cutaneus; the third branch, which accompanies the mufcles of the fcapula under the fkin, defeends to the humerus, without producing any remarkable branches. At this place, however, it fends off feveral ramifications to the extenfor mufcles of the fore-arm. The trunk continues its direction forward, expands and lofes itfelf under the fkin, and may be followed as far as the hand: it may, perhaps, be regarded as fupplying the place of the ulnar nerve.

The fixth pair of cervical nerves having, as we have fhewn, affifted in forming the brachial plexus, paffes along the internal furface of the fcapula; about the lower third of that bone it receives the feventh pair; the nerve then becomes thicker, but foon after divides into two branches; one, which is flender, paffes into the groove, between the furca and the clavicle, and then fpreads over the articular capfule of the humerus, after furnifhing numerous filaments to the mufcles which furround it; the nerve may be regarded as analogous to the articular in man. The trunk of the nerve, which evidently fupplies the place of the median, upon reaching the articulation of the humerus with the fcapula, tranfmits filaments to the adjoining mufcles. On arriving at the palmar furface of the fore-arm, it divides into three portions, two of which are on the ulnar fide, and fink deeply into the mufcles; the third, which is much larger, follows the radial fide of the fore-arm, and at the bafe of the thumb proceeds to the palm of the hand, and detaches filaments to each of the fingers.

The feventh cervical pair unites, as we have ftated, to the fixth, at the pofterior part of the fcapula, to form the median and articular nerves. We have, therefore, no occafion to return to its defcription. The firft dorfal pair is loft in the mufcles of the fhoulder, and is not continued throughout the arm.

The brachial plexus of the lizard differs a little from that of the tortoife; it is formed by two dorfal, and the two laft cervical pairs: the firft of the cervical furnifhes only one of its branches to the plexus; the other going to the neck.

In

In the frog, the nerves, which are to be diſtributed to the arm, proceed from a very thick cord, which comes from between the ſecond and third vertebræ: this makes the largeſt nerve in the whole body; it is ſoon after joined by a filament from the ſucceeding pair, with which it intimately unites; this cord proceeds towards the axilla; it ſends off a branch, which paſſes above the ſhoulder, and is loſt in the muſcles of that part. The trunk continues its courſe to the arm, and very ſoon forms two principal branches, and beſides theſe, it alſo ſends ſome filaments to the extenſors of the fore-arm, and the articular capſule of the head of the humerus.

Of theſe two nervous cords, one is directed forward upon the humerus, and repreſents the median nerve; it detaches ſome filaments to the muſcles of the ſkin. Arrived at the fold of the fore-arm, the nerve plunges amongſt the muſcles, along with the tendon of the ſterno-radialis, which ſupplies the place of the biceps; it afterwards divides into two branches, placed one above the other: the moſt ſlender is ſituated between the flexor muſcles of the fingers; the larger upon the furrow, which indicates the union of the two bones of the fore-arm; they paſs under the ligaments of the carpus; having reached the palm, the ſuperficial branch is loſt in the ſkin, which covers that part, and the deep-ſeated is diſtributed to each of the fingers, nearly as in man. It alſo furniſhes ſome filaments to the muſcles of the hand.

The other cord repreſents the radial nerve; it turns round the humerus, and furniſhes, in the firſt place, ſome branches to the extenſor cubiti; continuing to deſcend round the humerus, it arrives before the articulation with the bone of the fore-arm: it is afterwards divided; one of the branches is loſt under the ſkin, the other paſſes under the back of the hand, and terminates on the convexity of the fingers. From this deſcription it will appear, that the nerves of the arm in frogs very much reſemble thoſe of the wing in birds.

In the ſalamander, the nerves of the arm are diſtributed as in the frog, but the brachial plexus is formed by two cervical, and two dorſal pairs, if we may regard as dorſal vertebræ, thoſe which ſuſtain rudiments of the ribs.

There are no brachial nerves in ſerpents.

Nerves of the hind Limbs.—In lizards, there is only a ſmall nervous filament, which proceeds from the femoral nerve, and ſupplies the place of the obturator. The femoral nerve is itſelf formed of the two laſt lumbar pairs, and paſſes above the bones of the pelvis to be diſtributed in the muſcles of the anterior part of the thigh. The ſciatic nerve is produced by the three pairs of nerves, which follow, and which alſo receive a filament from the laſt lumbar pair; the only cord they form proceeds along the inſide of the thigh, ſubdividing in the muſcles, and extending to the toes.

The diſtribution of the nerves in the abdominal member is nearly the ſame in the ſalamander; there are no differences, except in the manner in which the plexus is formed. The femoral is produced by a ſingle lumbar pair, which tranſmits a branch to the ſciatic plexus, formed by the two ſucceeding pairs.

In the frog, three pairs of nerves enter into the compoſition of the femoral plexus, before which they run the whole length of the oſſa ilii, which are very long: when arrived at the thigh, the plexus ſends off a nerve, which correſponds to the anterior femoral; it is diſtributed in radiated filaments to the fore part of the thigh. The reſt of the plexus proceeds into the pelvis, and forms a large cord, which paſſes to the poſterior part of the thigh, and may be regarded as the ſciatic nerve. A great number of filaments are afterwards detached from it to the muſcles: about the middle and poſterior part it divides into two branches, which paſs under the ham, and repreſent the two popliteal nerves, the external and internal: theſe are afterwards diſtributed to the foot of the poſterior leg, nearly in the ſame manner as to the human foot.

Great Sympathetic Nerve.—There is no deſcription of the diſtribution of this nerve in reptiles, except in the mud tortoiſe; in which animal it was diſſected by Cuvier. It is only diſtinct in the interior of the back-ſhell; it has a diſpoſition analogous to that of the cervical ganglion. The pneumo-gaſtric nerve, however, adheres ſo cloſely to it, that they cannot be ſeparated: we did not perceive any filament on the neck, which could be regarded as the trunk of the nerve.

On the peritoneum, and on the bodies of the vertebræ, there appear very diſtinct nervous ganglia, which are manifeſtly produced by the great ſympathetic.

The ganglia are exactly ſimilar to thoſe of birds. There are two ſuperior and two inferior filaments, which paſs under the tranſverſe proceſs of the vertebra, that is united to the back-ſhell: from the internal edge of each ganglion, a ſplanchnic nerve proceeds, which forms a plexus round each of the arteries produced by the aorta; one is alſo ſent to aſſiſt in forming the pulmonary plexus.

This nerve may be very eaſily traced to the internal parts of the firſt vertebra of the tail.

Phyſiology of the Nervous Syſtem.—The obvious differences of ſtructure between the warm-blooded animals and reptiles, in this ſyſtem; the exceedingly ſmall brain and large nerves of the latter, contraſted with the ſlender nerves and large encephalon of the former, lead us to expect no leſs ſtriking differences in their economy, than thoſe which we actually diſcover. Are we to explain by this difference the little influence that the brain exerciſes over the other functions, and the great individual and independent vitality, if we may uſe the expreſſion, of the parts, which appear in ſo many inſtances in the amphibia? The ſevereſt injuries, which in man or the warm-blooded animals would excite a ſympathetic diſturbance of every function, highly dangerous, and in moſt caſes fatal, are borne with little apparent ſuffering, and reſtored with facility. (See the facts adduced in the phyſiology of the circulating ſyſtem, to prove the tenacity of life in this claſs.) Can we explain in the ſame way the reproductive powers of this claſs? Blumenbach ſeems to conſider the explanation ſufficient. "The extraordinary ſtrength," ſays he, "of the reproductive power in ſeveral amphibia, and the aſtoniſhing facility with which the proceſs is carried on, muſt be explained, if I miſtake not, from the great magnitude of their nerves, and the diminutive proportion of their brain. The former parts are in conſequence leſs dependent on the latter; hence the whole machine has leſs powers of motion and diſplays leſs ſympathy: the mode of exiſtence is more ſimple, and approaches more nearly to that of the vegetable world, than in the warm-blooded claſſes: but, on the contrary, the parts poſſeſs a greater individual independent vitality. Since, in conſequence of this latter endowment, ſtimuli, which operate on one part, or one ſyſtem, do not immediately affect the whole frame by ſympathy, as in warm-blooded animals, we are enabled to explain the peculiar tenacity of life, which is diſplayed under various circumſtances in this claſs; *viz.* frogs continue to jump about after their heart has been torn out; and tortoiſes have lived for months after the removal of the whole brain from the cranium. The long continued power of motion in parts which

which have been cut off from the body, as in the tail of the water newt, and in fragments of the blindworm, may be explained upon the fame principles." Handbuch der Naturgefchichte, ed. 6. § 98. p. 221.

The clofe connection between the brain, heart, and lungs in warm-blooded animals, in confequence of which the ceffation of action in one very fpeedily ftops the others, and confequently brings on general death, has been fully explained in various articles of this Dictionary; *viz.* DEATH, HEART, LUNGS, NERVOUS *Syftem*.

Obfervations and experiments have not yet been fufficiently multiplied, to enable us to underftand all the minutiæ connected with this fubject. But obvious phenomena, which we have already alluded to, fhew us a vaft difference in this refpect between mammalia and reptiles. The interruption of refpiration, which is fatal in two or three minutes in the human fubject, does not ftop the action of the heart and brain until after fome hours in reptiles. The removal of the heart, or of all the blood from the circulating fyftem, does not prevent the action of the brain, and thus prove fatal, until after fome hours. And, laftly, the removal of the whole brain, or decapitation, which, by interrupting the action of the mufcles employed in breathing, is almoft fuddenly fatal in warm-blooded animals, does not very greatly affect reptiles. At leaft, they only feem to die from inanition after the operation. Hence breathing cannot be under the immediate influence of the brain in thefe animals, for its interruption is fatal in a few hours. Le Gallois afferts that death follows much more quickly, when decapitation is effected below the occipital foramen, than above it, becaufe in the latter cafe the part of the brain is left, which he has afferted to be neceffary to refpiration; *viz.* the origin of the eighth pair. (See his Expériences fur le Principe de la Vie, p. 42.) He does not, however, afford us the materials of drawing any accurate comparifon, and he allows, that when decapitation is performed in the firft vertebra of the neck, the animal furvives the operation much longer than it can furvive the interruption of refpiration. He fays, that falamanders live three or four months, and feem to die only from inanition, when decapitation has been performed above the foramen magnum.

To the fmall influence of the brain upon the nerves, Blumenbach is inclined to refer, in fome degree, the low temperature of reptiles. Although he confiders it now as certain, that the lungs are the fource, and the oxygenous part of the atmofphere the material, whence the heat of living animals is derived, he afcribes to the action of the nervous fyftem a confiderable influence in exciting and fupporting the evolution of animal heat. Specimen, p. 22.

The brain feems to exercife as complete and prompt a dominion over the voluntary mufcles in thefe, as in warm-blooded animals. Their motions are equally lively, and the force of contraction does not feem at all inferior.

We know of very few facts that throw light on the intellectual faculties of reptiles. Yet there is fufficient evidence of their poffeffing memory and a capability of inftruction. The frog and tree-frog can be taught to feed from the hand; and acquire a flight attachment to their mafter. (Daudin, v. 8. p. 88.) The rattlefnake, the hooded-fnake (col. naia), the boæ, and the coluber natrix in Europe (at leaft commonly in Germany), are taught to dance, and exhibit various motions at command. (Kæmpfer, Amœnitates Exoticæ, p. 565.) In the hiftorical accounts of the religion of ancient Egypt, we learn that the priefts of Memphis bred up crocodiles in their temples, and fucceeded fo far in depriving them of their ferocity, as to employ them in religious ceremonies. Befides the accounts of Herodotus, Strabo, &c. on this fubject, we have the authority of a refpectable eye-witnefs concerning very furprifing fuccefs in taming a crocodile; fee J. Greaves's Mifcellaneous Works, p. 525: and for the like fuccefs in the common toad, fee Blumenbach, Specimen, &c. p. 27. We know not on what grounds the ferpent gained his character for wifdom, intelligence, forefight; why he was felected as an emblem for the goddefs of prudence, or chofen by the Epidaurians as the reprefentative of Efculapius.

Of the artificial inftincts, which are fo frequent in the mammalia and birds, not even a trace is to be met with in the whole clafs of reptiles.

There is no *regular fleep*, or intermiffion of activity, in the organs of fenfation and voluntary motion, recurring at ftated intervals, in reptiles: unlefs, perhaps, in the turtles, of whom it has been reported by fome.

Winter fleep, on the contrary, feems to prevail through the whole clafs. Herodotus obferved this of the Nilotic crocodile, which, he fays, paffes four months of the winter without eating. Catefby has remarked it of the crocodile of Carolina; and Lacoudrenier reports, that thofe of Louifiana betake themfelves to the muddy marfhes when the cold comes on, and remain fo torpid, that they may be cut without fhewing figns of fenfibility. But the warm days of winter re-animate them. Journal de Phyfique 1782, t. 20. p. 333.

No animals, except infects, are fo fenfible to heat as reptiles. The warmth of the fun feems to give them new life: as it increafes, their vivacity and agility are augmented. Cold, on the contrary, benumbs them, and would be actually deftructive, if they did not withdraw from its pernicious influence. They retire into the crevices of walls or rocks, the hollows of old trees, holes in the earth, or the bottoms of ponds, &c. to await the return of the genial feafon. The phenomena of this winter fleep are the fame in reptiles, as in warm-blooded animals. The fufpenfion of the actions of the nervous fyftem is followed by an univerfal torpor of the other functions. As the brain and the organs of voluntary motion become inactive, the circulation languifhes, refpiration is barely continued, and vital temterature is reduced to the loweft degree.

Spallanzani found that when the temperature was reduced to $1\frac{1}{2}°$ below zero, the heart of a ferpent beat only twice in a minute, and refpiration was fufpended. (Rapports de l'air avec les etres organifés, t. 1. p. 230.) In a temperature of 7°, the heart foon recovered its action, and beat ten or twelve times in a minute: in ftill higher temperatures, the pulfations were 28 or 30 *per* minute. (Ibid.) In the lethargic ftate, thefe animals changed the air very little. Frogs became equally lethargic in reduced temperatures; the heart beating very flowly, and the air being flightly changed. Ibid. p. 470.

Cold appears to be the immediate caufe of this winter torpor; hence both reptiles and warm-blooded animals may be preferved in fituations artificially warmed throughout the period of their winter fleep, without becoming torpid; but if the torpidity has commenced, they cannot be artificially awakened without danger. It is well known that the falamander, the water-newt, the tree-frog, and the alpine marmot, may be kept awake through the winter in a room warmed by a ftove. Gleditfch witneffed the fatal effects of violent excitement in the winter fleep in the frog (Mem. de l'Acad. de Berlin, 1762, p. 17.): it has been obferved alfo in the marmot, the dormoufe, and the fwallow.

It may be remarked further, of warm-blooded animals, as well as reptiles, that fome fpecies affemble together, and are gregarious in their torpidity, while others are folitary.

The

The bat, ſwallow, frog, and ſalamander, exemplify the former.

Organs of the Senſes.

Organ of Viſion.—Reptiles, like all vertebral animals, have two moveable eyes occupying the cavities of the head called orbits, and poſſeſſing in their ſtructure the ſame eſſential parts as in man. Their ſtructure has not been much inveſtigated: there is ſome information in a memoir of Petit, in the Acad. des Sciences, 1737; and an account of the tortoiſes in Caldeſi.

They occupy the ſides of the head, except in the crocodile, where they are placed above, between the cranium and jaw.

In the proteus they are covered by the integuments, and thus concealed until the latter are removed: this animal is, therefore, like the zemni or mus typhlus among mammalia, and conſequently blind. All other reptiles have the ſenſe of ſight, and ſome poſſeſs even large and prominent eyes.

The tortoiſe has, at the anterior part of the ſclerotica, ſimilar oſſeous laminæ to thoſe of birds. They are incloſed in that membrane, without being continued into its ſubſtance, and may be eaſily ſeparated from it. There are ſimilar laminæ in the cameleon and ſeveral other lizards, but they do not form the anterior diſk, they merely ſurround the lateral part. Daudin has found this ſtructure in the common iguana and the great tupinambis of America.

"In the tortoiſe," ſays Cuvier, "the ciliary proceſſes project ſo very little, that we could ſcarcely recognize them, were it not for the elegant impreſſion they leave on the vitreous body; but in the crocodile theſe proceſſes are very beautiful, and very conſpicuous: they are each terminated by a nearly right angle. I have obſerved theſe proceſſes in the form of elongated threads in a large foreign tree-frog; there are alſo ſuch, though not diſtinct, in the toad. I have not obſerved them in the common lizards, nor in the ſerpents.

"The iris of reptiles reſembles that of fiſhes in its golden colours; ſometimes it is red or browniſh. The veſſels are more viſible than in fiſh; they form a beautiful net-work on the iris of the crocodile.

"The figure of the pupil varies; in the crocodile it is vertically oblong, as in the cat: in frogs rhomboidal. The tortoiſe, cameleon, and common lizards, have it round; the gecko rhomboidal.

"The optic nerve in all reptiles paſſes through the membranes of the eye directly, and by a round hole, as in quadrupeds; it forms internally a ſmall tubercle, from the edges of which the retina proceeds.

"The cryſtalline is more ſpherical in the turtle and frog, than in the mammalia: the ratio of its axis to its diameter is in the former 7 to 9, in the latter 7 to 8: theſe proportions are nearly thoſe which it has in fiſhes."

Muſcles of the Globe.—There are ſix in the tortoiſe, diſpoſed like thoſe of fiſhes: and beſides, four ſmall ones, which cloſely embrace the optic nerve, and ſpread over the convex portion of the ſclerotic, after being interrupted by the muſcle of the third eye-lid. The ſame ſtructure is found in the crocodile.

In frogs and toads there is a great funnel-like muſcle, which embraces the optic nerve, and is divided into three portions; its inferior fibres advance more towards the edge of the eye than the ſuperior. There is only a ſingle ſtraight muſcle on the inferior part, and conſequently only a ſingle depreſſor. There is one very ſhort oblique muſcle attached to the anterior part of the orbit, and inſerted directly into the adjoining part of the globe. The muſcle of the third eye-lid is ſo cloſe to the inferior part of the ſuſpenſory muſcle, that it becomes ſtretched when the latter ſwells; which accounts for the elevation of the third eye-lid when the eye is lowered.

Blumenbach remarks, that no inſtance of the leucæthiopic formation, or deficiency of the colouring matter of the choroid coat and iris, has ever been ſeen in reptiles; although it is ſo common in the two warm-blooded claſſes, and in the human ſubject. Specimen, p. 27.

Many reptiles ſhun the light, lying hid by day, and coming out to ſeek their food at night. Others appear very fond of light, whether that of the ſun, as the green lizard and green frog; or of artificial flame, like that of a candle, as the tree-frog.

It ſeems peculiar to the cameleon to have the power of moving the two eyes at the ſame time in different directions; ſo that he is not neceſſarily obliged, like other animals, to bring the two optic axes into the ſame direction.

Eye-lids.—Reptiles vary ſingularly with reſpect to the number and diſpoſition of their eye-lids: ſerpents have none; crocodiles and tortoiſes have three, and the third is vertical, as in birds: there are alſo three in frogs, but the third is horizontal like the other two. The third eye-lid is the part called membrana nictitans.

The crocodiles are remarkable for having bone in the upper eye-lid: in general there is only a ſingle bit near the anterior angle; but in the crocodilus palpebroſus the whole eye-lid is occupied by a plate divided into three pieces. See Cuvier in Annales du Muſeum, v. 10.

The horizontal eye-lids of crocodiles and tortoiſes cloſe exactly; they have each an enlargement at their edge, but no cilia; the third eye-lid is ſemi-tranſparent; it moves from behind forwards, and may cover the whole eye; it has only one muſcle, which is analogous to the pyramidalis of birds: it is fixed in the ſame manner to the poſterior part of the globe inferiorly. After having turned round the optic nerve, it repaſſes under the eye to ſend its tendon to that eye-lid; but there are neither the muſculus quadratus, nor its ſheath, as in birds.

In the other lizards there are alſo very remarkable varieties. The common lizards have, for eye-lids, a kind of circular veil extended before the orbit, and perforated by a horizontal fiſſure, which is capable of being cloſed by a ſphincter muſcle, and opened by a levator and depreſſor; its inferior part has a ſmooth round cartilaginous diſk, as in birds; there is, beſides, a ſmall internal eye-lid, but it has no proper muſcle; it is entirely wanting in the cameleon, in which animal alſo the ſlit of the eye-lids is ſo ſmall, that the pupil can ſcarcely be obſerved through it. The gecko has no moveable eye-lid; its eye is protected by a ſlight margin of the ſkin, as in ſerpents. A ſimilar diſpoſition ſeems to prevail in the ſcink.

Blumenbach has examined more particularly the ſtructure of the part which covers the front of the eye in ſerpents. "Theſe animals," he obſerves, "are commonly ſaid to throw off the external layer of the cornea with the reſt of their epidermis when they change their ſkin. On examining this matter more minutely in the coluber natrix, I find that that part of the epidermis, which is perfectly tranſparent and ſtretched before the eye, is not actually connected to the cornea, but ſeparated from it by a ſmall quantity of water. It is immoveable, ſo that the globe moves behind it, as behind a window." Specimen, &c. p. 26.

In frogs and toads the ſuperior eye-lid is only a projection of the ſkin, and almoſt immoveable; the inferior is more moveable, and has a ſwoln edge; but the third, which moves from below upward, is moſt employed by theſe animals:

mals: it is very tranfparent; it has one mufcle fituated tranfverfely, behind the globe, which forms a thin tendon on each fide of the eye, to be inferted into the free edge of the third eye-lid.

The falamanders have only two eye-lids, which are horizontal, flefhy, and little moveable; it appears that they may entirely cover the eye.

Reptiles vary as much with refpect to their lachrymal glands as to their eye-lids.

The fea tortoifes have a very confiderable gland at the pofterior angle; it is reddifh, granulated, divided into lobes, and extends under the arch which covers the temple.

In the frefh-water tortoifes we find two fmall blackifh glands, which alfo exift in toads and frogs; but their excretory ducts have not yet been accurately obferved.

Serpents, like fifhes, have no gland in the eye; they have, however, a peculiar ftructure near the eye, the office of which is not very obvious; the following account of it is given by fir Everard Hume.

"An oval cavity is placed at the inner angle of the eye in fome ferpents, the opening into which is within the inner angle of the eye-lid, and directed towards the cornea. In this opening there are two rows of projections, which appear to form an orifice capable of dilatation and contraction. Thefe cavities are lined with cuticle, which is fhed with the reft of that integument. From the fituation of thefe oval cavities, they muft be confidered as refervoirs for a fluid, which is occafionally to be fpread over the cornea; and they may be filled by the falling of the dew, or the moifture fhaken off from the grafs, through which the fnake paffes." Phil. Tranf. 1804, p. 75. with a figure.

Organ of Hearing.—Such an organ is poffeffed by all reptiles. Its conftruction varies confiderably in the different orders and genera: thefe varieties affecting the external or acceffory parts, as the tympanum, officula, &c. more than the effential portion of the organ, its membranous labyrinth, on which the auditory nerve is expanded. No reptile has any external ear; and the crocodile affords the only example of a kind of external meatus. Frogs, teftudines, and moft of the lizard kind, have a tympanum and Euftachian tube; but thefe parts are wanting in the falamander, and moft of the ferpents. The ear of the turtle, tortoife, frog, lizards, and ferpents, are defcribed and delineated by Brunelli in the Comment. Inftit. Bonon. v. 7. Comparetti has exhibited figures of the fame fubjects in his Obfervationes Anatomicæ de aure interna comparata, Patav. 1789, 4to. Scarpa has given moft beautiful engravings of the ear in the turtle, crocodile, green lizard, falamander, viper, and blind-worm, in his Difquifitiones de Auditu et Olfactu.

The Labyrinth.—The membranous labyrinth of the ear, in reptiles, is, in general, compofed, as in fifhes, of three canals and a fac; but there are fome fpecies which have an additional part.

In the falamanders, whofe ear, like that of fifhes, confifts of the labyrinth only, the three canals are fituated above the fac; they are depreffed fuperiorly, and form together a triangle which is almoft equilateral; each has its ampulla, and the fac contains a body of the confiftence of ftarch, as in the rays and fharks.

Frogs and toads differ very little from falamanders, with refpect to the membranous labyrinth; they have the fame parts in the fame pofition, and their fac alfo contains one amylaceous fubftance: their three canals form nearly a complete circle, by their junction with the fac.

Crocodiles and lizards have alfo three canals, but they are larger, and each approaches nearer to a perfect circular form: the fac is fituated proportionally more within the head; its membranous parietes are furnifhed with feveral blood-veffels, which are particularly confpicuous in the crocodile. The folid parts it contains are three in number, and they are fmaller, and even fofter, than thofe of the chondropterygious fifhes. Laftly, their labyrinth is rendered remarkable by having an additional part to thofe we have already defcribed: this is the firft veftige of the cochlea; it is the production of the fac, in the form of a cone flightly arched; it is directed, under the cranium, towards the middle line, and is divided into compartments, or rather canals, by a double cartilaginous feptum; one apartment communicates with the fac; the other, which is a continuation of the firft, reflected on itfelf, terminates at a very fmall hole, which is clofed by a membrane that feparates it from the cavity of the tympanum.

This organ is precifely fimilar to that which is found in all birds. Comparetti was the firft who defcribed it in lizards. It is very large in the crocodile, and may be eafily prepared from young fubjects.

It is more difficult to find this in the cameleon and the marbled lizard. A veftige of it may be obferved in the ferpents. The production which may be compared to this trumpet, or rudiment of the cochlea in the tortoife, is very fimilar to the part we named the fac, ftrictly fo called, in fifhes; and this refemblance confifts not only in its form, but in the fmall amylaceous fubftances it contains: this feems to leave no doubt of the analogy between the fac and the cochlea in man, or of that between the part we call the finus, and the veftibule. We muft, therefore, judge of the perfection of the labyrinths of thefe different ears, by the degree in which the cochlea is developed.

Tortoifes and ferpents have the femi-circular canals, like other reptiles. In the tortoife they are proportionally very fhort.

The *offeous labyrinth* of reptiles refembles that of the chondropterygii; that is to fay, it envelopes the whole of the membranous labyrinth, but in a manner more or lefs clofely.

In the tortoife, the feptum, which feparates the veftibule from the cranium, is not offified; it remains partly membranous. The membranous femi-circular canals are much fmaller than the bony cavities containing them.

In the crocodile and other lizards, the offeous labyrinth clofely embraces the membranous, or completely covers it by a thin and hard lamina.

Cavity of the Tympanum and its Appendages.—Among reptiles, the falamander has the labyrinth completely inclofed within the cranium, and deprived of all external communication, as in the fifhes that have fixed branchiæ. But the other genera of the fame order have all a feneftra, called *oval,* fupporting an offeous plate, analogous to the bone called ftapes in man. The lizard genus has another aperture, clofed only by a membrane, and called feneftra rotunda.

The barrel, or cavity of the tympanum, cannot be faid to exift in ferpents: the ftalk of the plate, filling the feneftra ovalis, is furrounded by the flefh, and its extremity touches the fkin, near the articulation of the lower jaw.

In toads and frogs, the whole of its pofterior part is membranous; it communicates immediately with the back of the mouth, by a large hole, which may be feen on opening the mouth of the animal. It is very fmall, and almoft entirely membranous in the pipa, in which the labyrinth is connected with the feneftra ovalis by only a very long canal.

It is alfo membranous pofteriorly and inferiorly in the common lizards, and in the cameleon: it communicates with the bottom of the palate by a fhort wide canal.

The

The barrel of the crocodile may be divided into two parts: one external, which is very wide, and clofed on the outfide by the membrane of the tympanum, and the fkin, but entirely furrounded by the bones; and one internal, which is feparated from the former by a contraction, and which communicates with the two feneftræ, and with fome cavities analogous to the maftoid cells of man, but much larger. One of thefe cavities is placed between the femicircular canals, and the other is directed backward and outward. The barrel is fituated towards the fuperior part of the cranium.

The cavity of the tympanum in the tortoife is placed more laterally: it is not fo wide externally; and the contraction, which feparates the external part from the internal, is lefs confpicuous, becaufe the projection, which it forms, is rounded, and not acute, as in the crocodile. The internal portion is prolonged backward, in the form of a large round cell: in the bottom of the cavity, oppofite to the membrane of the tympanum, there is a narrow canal, in which the officulum is funk, and which communicates with the feneftra ovalis. The Euftachian tube is a canal of a moderate length, which proceeds downward, and a little backward, and terminates in the palate, behind and within the articulation of the jaw.

The Membrana Tympani and its offeous Frame.—Animals which want the barrel of the tympanum, as fifhes, falamanders, &c. have no membrana tympani. That membrane is alfo wanting in feveral reptiles that have a barrel, as the cameleon: the fkin paffes over the external aperture of their ear, without undergoing any change, either in its thicknefs or its ftructure; and the exiftence of the organ of hearing can only be afcertained by diffection. On removing the fkin, and fome portions of the mufcles, we find, in fome fpecies, and particularly in the flow-worm (anguis fragilis), a kind of membranous expanfion.

In the tortoife, the large external aperture of the barrel is clofed by a very thick cartilaginous plate, which is itfelf covered by a fcaly fkin, perfectly fimilar to that of the reft of the head.

In frogs and toads, the membrana tympani is on a level with the head, and the fkin that covers it becoming finer, it is rendered perceptible by an oval fpot, which is fmoother than the reft of the head, and ufually of a particular colour.

In common lizards, the membrana tympani is alfo level with the head, but very thin, fmooth, and tranfparent; for at that part the fkin becomes as fmooth and fine as the cornea of the eye.

In the crocodile, it is of the fame nature, but more funk into the head, and covered by two flefhy lips, which fupply the place of the external ear.

In lizards, though the point of the cone formed by the membrana tympani projects lefs than in birds, it is alfo directed outward, as in them. The membrane is nearly plane in frogs and tortoifes.

The membrana tympani is on a level with the adjacent parts of the head, and confequently is nearly vertical in all animals in which its fituation is fuperficial; but in thofe which have it funk, its inclination, whether confidered with relation to the head itfelf, or to the external meatus, varies confiderably.

It inclines obliquely upward, and to one fide, in the crocodile.

The offeous frame, to which the membrane is attached, is not marked by any prominent edge: it is interrupted pofteriorly. Its great axis is vertical in the tortoife and the common lizards, and its anterior arch is more convex. In the crocodile, it is a regular oval, the great axis of which is directed obliquely backward.

Officula Auditus.—The frog and the toad have two officula in the ear: one fupplies the place of the malleus and the incus; it is attached to the membrana tympani by a flender branch, which forms an acute angle with the part that paffes into the barrel: that part has the fhape of a club; its internal extremity is the thickeft, and articulates by a double furface to the fecond officulum, which correfponds to the ftapes. The latter has a femi-elliptic form, and is applied to the feneftra ovalis by its plane furface: both thefe bodies, which are offeous in other animals, are cartilaginous in the frog and toad.

Lizards and tortoifes refemble birds, in having a fingle officulum with a thin hard ftalk, and an oval or triangular plate (columella). It is attached to the membrane of the tympanum in lizards, and particularly in the crocodile, by a cartilaginous branch; but in the tortoife, its outward extremity is directly implanted in the cartilaginous mafs, which correfponds to the membrana tympani itfelf.

In the crocodile, the plate is an elongated ellipfis, the great axis of which is fituated longitudinally.

In the tortoife, the bone is enlarged in the form of a trumpet, and is applied to the feneftra by a regularly oval and concave furface.

Serpents have an officulum, but no membrana tympani. Its external extremity touches the bone that fupports the lower jaw: it is furrounded by the flefh, and is applied to the feneftra by a concave plate, the edges of which are irregular.

In the cameleon, the plate alfo reprefents the wide end of a trumpet; its ftalk becomes cartilaginous, and is loft in the flefh.

The feneftra veftibularis of falamanders is clofed only by a fmall cartilaginous operculum, which has no ftalk, and is concealed by the flefh.

Mufcles of the Officula.—Little is known about thefe in reptiles. It appears that ferpents, cameleons, and falamanders, are entirely deftitute of them, and that they are very indiftinct in the teftudines. Comparetti has made fome refearches on this fubject, but without any clear or fatisfactory refults.

External Meatus, &c.—All parts of the ear, external to the membrana tympani, are wanting in reptiles. In the crocodile only is there any appearance of an external meatus, the fkin forming a kind of lip or operculum above the membrana tympani: the latter is entirely concealed, except when this covering is removed. This muft be the part mentioned by Herodotus as the external ear of the crocodile, to which the Egyptians attached rings.

Diftribution of the Nerves.—In reptiles and fifhes, but efpecially in the latter, we can obferve, ftill better than in warm-blooded animals, the conftancy with which the branches of the auditory nerve proceed to the ampullæ of the femi-circular canals. In reptiles it divides before it paffes into the offeous labyrinth, which it enters by feveral holes.

Organ of Touch and Integuments.—It does not feem clear that reptiles poffefs the fenfe of touch, that is, the power of recognifing, by any parts of their fkin, the figure, hardnefs or foftnefs, roughnefs or fmoothnefs, of bodies. To the impreffions of heat and cold, there is no doubt of their being fenfible.

In no clafs do we obferve fo much variety in the nature of the integuments; the fkin is different in almoft every fpecies. In many the ftructure is fo fingular, that if we judged by this alone, we fhould form them into feparate claffes. What

a contraft

a contraſt does the ſhell or bony caſe of the tortoiſe form to the ſmooth ſkin of the tree-frog; how different are the annulated ſkin of the amphiſbæna, the ſcaly covering of other ſerpents, and the integuments of the toad, rough and tuberculated.

Epidermis.—When we examine what parts of the body are covered with ſkin in the tortoiſe and turtle, we can recognize it at firſt ſight only on the head, neck, limbs, and tail; the other parts exhibit to us merely an oſſeous box or exterior ſkeleton, incloſing the body. But, if we examine more attentively, we ſhall find this ſkeleton covered by an extremely thin epidermis, which may be detached in tranſparent laminæ, ſimilar, in figure, to the horny plates, and varying in its conſiſtence in the different ſpecies. It reſembles a ſmooth and tranſparent parchment in the teſtndo centrata of Boſc (Daudin, t. ii. p. 153.) The epidermis covering other parts of theſe animals is a ſmooth thin layer, not eſſentially different from that of the frog and ſalamander, and detached in ſhreds ſeveral times in the year.

The epidermis of the ſalamander and frog is a ſoft thin membrane, covered with a mucous ſecretion; which anſwers a particular uſe in ſome kinds, as the rana calamita, enabled by its aſſiſtance to adhere to the ſmootheſt bodies. This ſecretion, a ſimple and innocent mucus, is very different from another, which is found in many reptiles, poſſeſſing extremely powerful ſenſible properties; the latter is deſcribed under the head of peculiar ſecretions, in the latter part of this article.

The thin tranſparent cuticle of the frog, ſalamander, and newt, is very frequently changed, being detached in large portions. Blumenbach ſtates that this change takes place in the ſummer months at leaſt once a week. Specimen, p. 26.

The epidermis of lizards covers all their ſcales, and is detached in ſmall dried portions, or in larger pieces. It forms alſo a thin continuous ſtratum in ſerpents, enveloping the whole ſurface, and ſpread over every ſcale and plate. It is detached annually, at a certain ſeaſon, in a ſingle piece, like a ſheath. The caſt ſkin (ſlough, exuviæ) is turned inſide out, ſo that its exterior ſurface is the part previouſly in contact with the true ſkin. The animal eſcapes at the mouth, which is the only opening by which it can get out of the ſheath. The part correſponding to the jaws is firſt detached, and turned back, ſo as to expoſe to us the ſnout, covered by a new ſkin. As the head paſſes out of its ſheath, the latter goes backwards in the ſame proportion towards the tail, and is thus at laſt completely inverted. The tranſparent piece correſponding to the eye (ſee an account of the eye) has its concavity outwards.

Rete Mucoſum.—In all reptiles there is, under the epidermis, a mucous tiſſue, of which the colours vary very much. In the teſtudines, for inſtance, the ſkin which covers the feet and neck is not only differently coloured by the rete mucoſum, but the ſymmetrical ſpots, which we remark on the ſcales, are produced by the ſame ſubſtance. This we diſcover by diſſection. The thickneſs of the ſkin greatly diminiſhes as it approaches the breaſt-plate and the back-ſhell. It paſſes below the ſcales which cover thoſe parts, and which are, themſelves, covered by the epidermis and rete mucoſum; the variegated colours of which form the ſpots which we obſerve through the tranſparent parts. A rete mucoſum is equally found in the lizards, ſerpents, ſalamanders, frogs, &c. It is variouſly coloured in each ſpecies; and it preſents often the moſt beautiful and charming tints. We find in this claſs almoſt all the known ſhades, even blue, bright red, orange, pearly, gold and ſilver.

Reptiles are remarkable for the changes of colour which they exhibit, according to the ſeaſon or climate in which they live, or to temporary affections of various kinds. In this way the cameleon has been moſt celebrated, and has afforded a very trite ſubject to poets and moraliſts. The changes are, in reality, very remarkable, and are particularly noticeable when the animal paſſes from the ſhade into the ſun, or *vice verſâ*, when he is touched, or any thing placed round him, &c.

This property, however, is, by no means confined to the cameleon. Brown long ago obſerved it in ſeveral ſpecies of lizards (Natural Hiſtory of Jamaica, p. 462.); and it occurs alſo in reptiles of theſe climates. The green iguana, the agame, and the green lizard, are ſometimes green, ſometimes browniſh in their colour. The former is particularly obſerved in the copulating ſeaſon; and is loſt in the cold and rainy parts of the year. The common tree-frog of Europe exhibits various tints from the brighteſt emerald green to grey, blueiſh, violet, or brown. Other frogs and ſalamanders change their colours alſo, particularly about the copulating ſeaſon.

The Papillæ.—Reptiles reſemble birds with reſpect to the papillæ; we find none except under their feet; they are very thick, and projecting in ſeveral ſpecies of lizards, and particularly in the cameleon. We cannot diſtinguiſh them in the ſea tortoiſe, which have the feet in the form of fins. They do not exiſt in ſerpents, or at leaſt have not the form of papillæ.

Cutis.—Reptiles which have the body unfurniſhed with ſcales, or only partly covered by them, have a very compact and denſe ſkin. We have an example in the tortoiſes, ſalamanders, frogs, and toads. In the two laſt genera, in particular, the cutis is rendered remarkable by not adhering to the body in all its points, as in the other animals, in which it is intimately united with the cellular ſubſtance. In thoſe genera, however, it adheres only at the edges of the mouth, in the middle line of the body, the arm-pits and the groins. In all the other parts the body is free within the cutis, which incloſes it like a ſac.

In lizards and ſerpents we find, as in fiſhes, a ſtrong cutis under the ſcales, even adhering very cloſely to the muſcles.

Cutaneous Muſcles.—There is no cutaneous muſcle on the trunk of frogs, becauſe the ſkin does not adhere to that part of their body. Under the throat, however, we find ſome fibres, which are attached to the margin of the jaw, and inſerted into the cellular ſubſtance that unites the ſkin to the origin of the breaſt.

In tortoiſes the cutaneous colli is very viſible, and ſeems to be formed of two parts; it is extended from within the concavity of the lower jaw to the bottom of the neck, at the anterior part of the breaſt-plate. A middle cellular line unites it with the muſcle of the other ſide; it takes its origin from the tranſverſe proceſſes of the cervical vertebræ. Being ſpread over all the muſcles of the neck, it ſerves as a girdle to them; in its lower part it is perforated by the ſterno-maſtoideus, which, as we have already obſerved, ariſes from the lateral parts of the breaſt-plate.

Secretions of the Skin.—Among reptiles, thoſe that have ſcales, as ſnakes and lizards, have the ſkin almoſt dry; but thoſe with naked ſkins, as ſalamanders and frogs, have the ſurface of the body always copiouſly lubricated with viſcous matter.

Toads and ſalamanders have even the power of augmenting the ſecretion of this liquor, and of making it exude, like a dew, through the pores of the ſkin.

The cutaneous glands are more viſible in cold-blooded animals, than in the mammalia.

The

The ſalamanders have ſeveral glands ranged along the back, which form elevations or lumps on the ſkin.

The toads have them ſcattered irregularly on the whole ſurface of the body; we obſerve, in particular, two which are very large, behind their ears; theſe glands produce an acrid humour, which is a poiſon to very ſmall animals.

In lizards, we obſerve a very regular row of ſmall pores, which alſo yield a viſcous humour.

Abſorption of water by the ſkin of the frog.—Townſon found that the frog, and tree-frog, when placed on a moiſtened paper, could abſorb the moiſture ſo rapidly, as nearly to double their weight in two hours, under certain circumſtances. He ſtates that they do not drink, but take in all their fluid in this way. (See his tracts and obſervations in natural hiſtory.) Daudin has verified the obſervation. He kept two frogs without any fluid for ſeven days, and then placed them in a bottle on moiſtened ſheets of paper. In two hours they had nearly doubled their weight. Hiſt. Nat. des Reptiles, tom. i. p. 115.

Fingers.—The number of the fingers, and their flexibility, vary more in reptiles than in all the other claſſes.

Common lizards have, in general, five fingers, of different lengths, well calculated to embrace objects in every direction. Some, as the crocodiles, have them palmated, at leaſt in the poſterior feet. Others, as the gecko, have them inveſted inferiorly with imbricated ſcales.

The cameleon has them united by the ſkin, as far as the nails, in two parts, which form the forceps. The ſkin of their inferior ſurface is furniſhed with ſenſible papillæ. The long lizards, called ſeps and chalcides, have only three very ſmall toes. The ſalamanders and frogs have them naked and deſtitute of nails. In tree-frogs, the extremity of the toes is enlarged into a ſpongy diſk, capable of adhering with force to bodies. In tortoiſes, the toes are palmated. Laſtly, the ſerpents are completely deprived of feet and toes.

The long ſeparate toes of the batracian order, and of ſeveral lizards, ſeem well enough calculated to ſerve as organs of touch; they might be applied to objects, and would ſurround them in various ways. They ſeem, however, to be employed merely as inſtruments of motion.

"It has been ſaid of ſerpents (obſerves Blumenbach), with more ingenuity than truth, that their whole body is a hand; by which they gain juſt notions of the tangible properties of bodies. There is much more foundation for ſtating that the ſenſe of touch, which is here meant, does not exiſt in any of the amphibia." Syſtem of Comparative Anatomy, p. 319.

Among the reptiles the ſcales vary greatly, according to the genera. In tortoiſes they are plates of a horny ſubſtance, which are very hard and denſe in the greater number. But in the teſtudo coriacea, and ſeveral others, they are ſoft and flexible: ſometimes theſe ſcales are imbricated, as in the hawk's-bill turtle; and then they are ſmooth, or channelled longitudinally; at other times they form compartments of different figures: in the latter caſe they are more or leſs convex, and ſurrounded with furrows, or concentric channels, in the midſt of which are points, which are either ſcabrous, elevated, or blunt, as in the ſpecies named geometrica, græca, &c.

In the crocodile the ſcales are bony, arranged in tranſverſe bands, and ſituated, in reſpect to each other, like the ſtones of a pavement. In the other lizards and ſerpents they conſiſt of horny ſubſtance, and preſent almoſt every poſſible variety of form and arrangement.

Organ of Smelling.—This is leſs completely developed in the amphibia than in the two warm-blooded claſſes of vertebral animals. The ſenſe of ſmelling is the moſt imperfect of the ſenſes in this claſs, ſays Daudin, if we may judge by the ſtructure of the noſtrils. Reptiles do not ſeem to employ their ſmell in diſcovering or ſelecting their food, or for any of the purpoſes to which the faculty is ſubſervient in other animals.

We find, however, in the whole claſs, naſal cavities opening on the ſnout in front, and on the palate behind, lined with a vaſcular pituitary membrane, on which olfactory and naſal nerves are diſtributed.

There are alſo different projecting laminæ within the noſe; but they conſiſt of folds of the internal membrane, and are not ſuſtained by oſſeous parts. The tortoiſe has three laminæ, which divide the naſal cavity into ſeveral foſſæ. The middle one correſponds to the external aperture of the noſtrils; between it and the next there is an oblique canal, which leads to the poſterior nares. We find only ſome tubercles in frogs, and other ſmall ſpecies. It does not appear that any reſearches have been made reſpecting the parts in the crocodiles.

The olfactory nerve differs in reptiles little from that of birds, as to its origin and courſe; it differs leſs in its diſtribution, ſince it alſo divides, according to Scarpa, upon the ſeptum, and the membranous fold correſponding to the ſuperior turbinated bone, without proceeding farther.

The *external nares* of reptiles, more or leſs approximated, and ſuſceptible of contraction and dilatation, are uſually furniſhed with only ſome fleſhy ſtrata, which dilate or contract their entrance. This is obſervable in the greater number of lizards, which differ from each other only as to the poſition of their external nares. They are cloſeſt to each other in the crocodiles. The tupinambis, the ſtellions, and the cameleons, have them more removed, and ſituated more laterally. In the ſalamanders they are exceedingly ſmall. In frogs we obſerve a ſmall tube, the motion of which is very apparent, becauſe it is extremely uſeful in reſpiration, as we have already ſhewn. The tortoiſes have alſo two very ſmall approximated noſtrils. In the matamata, and one or two other ſpecies, they are ſituated at the end of a ſhort cartilaginous proboſcis. The external noſe is alſo rather elongated in ſome ſerpents; for example, in the vipera ammodytes, and the coluber naſica. In the reſt of this order there are ſmall lateral nares, capable of ſlight extenſion. In the rattle-ſnake, and ſome others, there is a ſmall blind hole, near the noſe, on each ſide; we have deſcribed it under the head of peculiar organs. See Scarpa de Auditu et Olfactu, for a deſcription and figures of the noſe in the turtle and viper.

The Organ of Taſte.—All reptiles poſſeſs a tongue, but whether they have the ſenſe of taſte is not ſo clear. As they all ſwallow their prey whole, there ſeems to be little room for the exerciſe of taſte. We have already ſpoken of the tongue, in the account of the ſalivary glands; and have entered further into a conſideration of its mechaniſm and moving powers in our deſcription of the organs of maſtication and deglutition.

Subſtance of the Tongue.—Reptiles vary greatly with reſpect to the tongue, as well as in many other circumſtances. The tongue of toads and frogs is entirely fleſhy, attached to the lower jaw, and, in a ſtate of repoſe, inflected in the mouth.

In ſalamanders, it is attached as far as the point, which is not moveable, and the whole tongue is only free on its lateral parts. Crocodiles have it attached to the lower jaw, both by the edges and the point; and authors long ſuppoſed that this animal had no tongue. It is entirely fleſhy in both theſe genera.

The ſtellions and the iguanas have a fleſhy tongue, which poſſeſſes nearly the ſame mobility as that of the mammalia.

 The

The feinks and geckos differ only in having the tongue notched at the extremity; and in that refpect it refembles the tongue of the flow-worms, to which, in general, the feinks are very much allied.

In common lizards, the tupinambis, or monitor, &c. the tongue is fingularly extenfile; it terminates in two long flexible points, though femi-cartilaginous; it completely refembles that of ferpents, if we except the flow-worms and the amphifbæna, which cannot elongate their tongue, but which have it flat, and only forked at the extremity.

The cameleon has a cylindrical tongue, which may be confiderably elongated by a mechanifm analogous to that which takes place in wood-peckers.

Structure of its Surface.—The tongue of the tortoife is furnifhed fuperiorly with long, foft, clofe, conic papillæ, which give it the appearance of velvet.

In the crocodile they are very fhort, and reprefent rather flight rugæ than papillæ. They form, on the contrary, a very diftinctly villous furface in the iguanas and the ftellions. The tongue of the cameleon is furnifhed with deep, clofe, and very regular tranfverfe rugæ; in the lizards, with extenfile and forked tongues; and in the ferpents, that organ is fingularly fmooth, and as it were horny towards its points.

The falamanders have, like the iguanas, a fine villous furface to the tongue; but in the frogs and toads the furface is perfectly fmooth to the eye, and always mucous.

No reptile has two kinds of papillæ, nor glands with a calyx.

Peculiar Organs and Secretions.—Many amphibia produce fingular and fpecific odours, particularly when irritated. In the water newts the fmell has been compared to that of chopped parfley; in toads to garlic; in the crocodile there is a very ftrong fmell of mufk; and feveral tortoifes have this mufk-like fmell. A fingularly fetid odour is produced by the rattlefnake, when angry. May we fuppofe that this is a defence againft hoftile attacks, in the falamanders and water newts, as it feems to be in the viverræ, and fome frogs?

It may probably ferve in fpring, as Blumenbach fuggefts, as a means of venereal excitement. For if, after handling female toads for fome time, the hand is plunged into water, where there are male toads, they flock inftantly to the fpot, and clofely embrace the fingers. Specimen, p. 29.

The notion that this odour is employed by the rattlefnake to fuffocate, fafcinate, or in any way whatfoever to act on the animals which form its prey, is entirely ungrounded, as we have already explained.

There are generally manifeft organs for the fecretion of the fubftances in which thefe properties refide. Small granulated tubercles are feen under the thighs of the lizards, the chalcides, and the marbled iguana of Surinam, and near the anus of the amphifbæna, producing, particularly in the coupling feafon, a fluid, and fmelling like dry hay.

Mufk Gland of the Crocodile.—It lies under the fkin of the lower jaw, on each fide, about its middle. It is a fmall gland, of a homogeneous whitifh tiffue, and covered by a tendinous fheath. It fecretes an unctuous blackifh-grey fluid, fmelling moft ftrongly of mufk, and collected in a fmall bag, which opens externally by a large orifice.

Anal Glands have alfo been obferved in the crocodile and alligator, as well as in feveral ferpents. They may be feen of confiderable fize in female colubres, under the tail behind the cloaca, in the part occupied by the penes of the males. They contain a thin yellow fubftance. Tyfon has defcribed them in the rattlefnake. Other fnakes have been defcribed as producing powerfully fetid odours from the mouth.

Poifonous and Acrid Secretions.—There is a ftriking difference in this refpect between warm-blooded animals and reptiles: none of the former produce any thing poifonous, unlefs we fhould make an exception concerning the liver of the urfus arctos, which is defcribed by Ger. de Veer, one of the unfortunate fufferers, to have been nearly fatal when employed as food by Heemfkerk and his companions, compelled to winter in Nova Zembla. Blumenbach's Specimen, p. 30.

Befides the terrible poifon with which fo many ferpents are armed, already defcribed in our account of the teeth, there are feveral more or lefs actively hurtful fecretions in this clafs.

The glands or crypts under the fkin, forming the cutaneous eminences in the falamander and toad, produce an irritating fluid, which they feem to have the power of excreting at pleafure. Blumenbach defcribes the acrimony of this fluid in the rana bombina, from his own experience of its effects. Having cut his hand while handling fome of thefe animals, and applied it to his mouth to fuck the wound, he found a cauftic heat fuddenly pervade the tongue and fauces, like what is produced by chewing the bark of the laurel; and it continued for feveral hours. P. 24.

It feems to be an analogous fluid in the falamander, by means of which this moft innocent little animal, fo unjuftly deemed venomous, can extinguifh a few coals when placed in them. But the contortions of the body fufficiently atteft the pain produced by this cruel experiment, which is foon fatal, if prolonged. The fabulous notion of the ancients, that this little reptile can live in fire, is well known; and Benvenuto Cellini has ventured to affert the truth of it, on the faith of his own experiments. See his Life.

The notion of the falamander being able to live in fire is the more extraordinary, when we contraft it with the fact, that it has been found in cakes of ice, and after remaining frozen for fome days, recovered. So that it can actually furvive congelation.

Dr. Barton of Philadelphia has named an aquatic falamander, which he found near that city, falamandra venenofa, from the nature of the fluid which exudes from the tubercles of its back. Daudin, tom. viii. p. 229.

The gecko of Egypt produces a poifonous fluid of confiderable activity. "It exudes (fays Haffelquift) from the lobules of the toes; the gecko feeks for places and objects impregnated with marine falt, and paffing feveral times over them, leaves its venom behind. I faw in 1750, two women and a girl, who nearly died in Cairo from eating cheefe which had been thus poifoned. I had another opportunity of noticing the acrimony of this fluid, in the production of red, inflamed, and itching puftules on the hand of a man, who endeavoured to catch the animal." The French naturalifts, attached to the Egyptian expedition, confirm the report of Haffelquift. Daudin, tom. iv. p. 110, 111.

Rattle of the Genus Crotalus.—This fingular organ confifts of many pieces, from one to thirty, or more, perfectly fimilar, not only in form, but often alfo in fize, compofed of a brittle, femi-tranfparent, horny fubftance, fimilar to that of fcales. The piece immediately connected to the body forms a fmall fheath, moulded on the laft vertebræ of the tail, which it inclofes, and from which it is feparated only by a thin membrane. Its furface prefents three circular rifings, correfponding to three elevations of the vertebræ: the firft, or neareft to the animal's tail, is the largeft, and the two others decreafe fucceffively. All the pieces are encafed one in the other, the pofterior two-thirds of each being enveloped by the following. Of the three rifings or rings on each piece, the anterior only is vifible, the two pofterior

terior being concealed by the following piece. The laſt, or extreme portion, has all its three rings viſible; and the organ conſiſts, externally, of this piece, and the firſt rings of all the others. The two laſt rings of each piece, included in the two firſt of the ſucceeding, retain it in its place; but, as the diameter of the former is leſs than that of the latter, each piece is quite looſe, and plays freely about that which it envelops. None, except the firſt, is united to the ſkin of the animal, or connected by any muſcle, nerve, or veſſel; it is, therefore, merely an exterior covering, moved, as any foreign body would be, when the end of the tail is agitated.

The different pieces of the organ are formed ſucceſſively on the ſkin of the tail, receiving from it the materials neceſſary for its developement, and adhering to it until its growth is complete. A ſecond piece, entirely ſimilar to the firſt, is formed under it, and detaches it from the end of the tail. It is puſhed backwards, leaving between its edge and the ſkin of the tail an interval occupied by the firſt ring of the new piece, of which the ſecond and third rings are covered by the firſt piece. The latter is retained by this connection, but plays freely round the firſt piece. A third piece is formed under the ſecond, as that was under the firſt; puſhing the ſecond backwards, but retaining it by its two poſterior rings being included in the cavity of the ſecond piece.

If the vertebræ of the tail continue of uniform diameter, all the pieces will be of the ſame ſize, and the rattle, conſequently, is of one breadth throughout. On the contrary, if the vertebræ grow while the rattle is being formed, the pieces increaſe in ſize, and thus the rattle tapers to its end.

It is evident, from the preceding deſcription, that one piece only can be formed at each partial moulting of the end of the tail; but as we do not know whether theſe moultings coincide with the general ſeparation of the epidermis from the body, nor the periods of their recurrence, the number of pieces not only affords no proof of ſpecific differences, but alſo indicates nothing about the age of the animal. Lacépéde, Hiſt. Nat. des Serpens, 12mo. t. 2. p. 217.

Horns, &c. of other Serpents and Reptiles.—The Egyptian ceraſtes is ſo named, from its two moveable, pyramidal, four-ſided, curved horns, about two lines in length, placed above the eyes. They conſiſt of ſucceſſive ſtrata, of which the exterior ſeparates like an epidermis, exhibiting always four grooved ſides. The exterior ſtratum ſeparates thus with the animal's ſkin, like the epidermis of the ſcales, which this reſembles entirely in its texture. Lacépéde, ubi ſupra, t. 1. p. 256.

In the batracian order, the horned frog has a conical horny elevation above each eye; and the rana margaritifera a peculiar hard criſta on each ſide of the head.

The cecilia ibiara has two ſmall tentacula or cirri, ſcarcely viſible near the noſtrils; and the ſerpent, which Lacépéde has named erpeton tentaculé (Annales du Muſeum, t. 2. p. 280.) has two fleſhy appendages, covered with ſcales, extending from the end of the ſnout horizontally forwards. Is there any probability that theſe parts in the cecilia and erpeton are organs of touch?

Facial Pouches of Serpents.—A ſmall bag has been obſerved in the rattleſnake, in ſixteen colubres, and three boæ, between the eye and the noſtril; it has a rounded form, reſting in a hollow of the bone, in ſhape not unlike the orbit. A ſmall orifice behind the noſtril leads to it. Theſe bags, which are lined with cuticle, have their covering caſt with the reſt of the animal's ſkin. The cavities in queſtion were noticed in the rattleſnake by Tyſon, Phil. Tranſ. v. 13. p. 26; and they have been ſince deſcribed and delineated by Dr. Ruſſel and ſir Everard Hume. (Phil. Tranſ. 1804, p. 70.) The latter anatomiſt diſcovered nothing like a ſecretory apparatus about them, nor any thing that could lead to conjectures concerning their office. They appear moſt analogous, in ſituation and ſtructure, to the ſmall bags of the deer and antelope, called by the French larmiers.

We conclude our review of the ſtructure and phyſiology of reptiles with the ſummary of the principal differences between their economy and that of the warm-blooded claſſes, which terminates the excellent "Specimen" of Blumenbach.

"Et calidis quidem animalibus a prima inde formationis origine ad ultimum uſque vitæ halitum phlogiſticus ut hodie audit proceſſus. Mammalium fœtui placentæ adminiculo, quæ fœtale phlogiſton materno elemento igneo commutat. Pullo incubato poroſæ teſtæ et albuminis ope, quæ itidem igneo pabulo aditum, phlogiſto vero ſuperfluo exitum concedunt. In lucem vero editis tum mammalibus tum avibus, perpetuo et alterno reſpirationis rhythmo.

"Internus porro huic phlogiſtico proceſſui cum reliquis functionum claſſibus nexus, maxime cum iis ſyſtematis nervoſi, ut hiberni mammalium veterni, phænomenis quæ ſupra tetigimus, veriſimillimus redditur.

"Ipſius porro nervoſi ſyſtematis ſumma cum reliquis functionibus conſpiratio, præſertim ope reactionis ſenſorii ab ea encephali portione pendente, quæ præter originis nervorum ſuper eſt.

"Ex his omnibus ſummus quidem functionum vigor, mobilitas ſumma, hinc corpus vivum infinitis modis innumerorum, et multifariorum ſtimulorum impetui et impreſſionibus ſuſcipiendis aptum: hinc præ ceteris omnibus ſumma hominis prærogativa, in quo, uti, pridem obſervante Hippocrate, confluxio una, conſpiratio una, conſentientia omnia, ita et omnium maximus et innumerus cum univerſa reliqua cum ambiente creatione nexus.

"Longe alia e contrario amphibiorum natura.

"Phlogiſticus proceſſus noſtratibus perexiguus lentiſſimus.

"Debilis etiam in omnibus amphibiis ſanguinis in encephali functiones influxus.

"Exigua porro parvi ſenſorii in craſſas nervas reactio.

"Minor hinc in univerſum conſenſus; minus unius functionis in alteram imperium.

"Minor hinc totius machinæ animatæ mobilitas.

"Verum eo major ab altera parte ſimplicioris iſtius vitæ tenacitas, quod parte una affecta, ſyſtemate uno afflicto, non tam facile reliqua in conſenſum trahantur.

"In univerſum ergo vita magis vegetativa, reproductioni—ut per utrumque organicum naturæ regnum conſtat—longe magis opportuna, quam quæ altioris ordinis facultatibus, conſenſibus, et complicatæ conſpirationis ſubtilitate viget." P. 36.

Anatomical Deſcription of the Proteus Anguinus, and Siren Lacertina.—See Cuvier, Récherches ſur quelques Reptiles douteux, inſerted in Humboldt's Recueil d'Obſervations de Zoologie et d'Anatomie comparée faites dans ſon Voyage, t. 1.

By the word *amphibious*, applied to animals, naturaliſts have meant to deſignate the power of living, and particularly of breathing, equally well in water and in air. In this ſenſe it cannot be applied, with propriety, to any of the animals who have received the appellation from the ancients, and moſt modern naturaliſts. Without ſpeaking of the otters and hippopotami, which are true aerial quadrupeds, viſiting the water merely in ſearch of food, the ſeals and cetaceous

 animals,

animals, compelled by their organs of motion to paſs the whole, or nearly the whole of their life in water, can abſolutely breathe air only.

All the reptiles to whom Linnæus ſubſequently transferred this name of amphibious animals, are ſimilarly circumſtanced in their adult ſtate; they can only breathe air, whether they live conſtantly in this element, as the lizard kind, or betake themſelves, for a longer or ſhorter period, to the water, as the frogs and ſalamanders. On the other hand, the cartilaginous fiſhes, which this ſame naturaliſt had joined to the reptiles, like all other fiſhes, can only breathe by the intervention of water; they have only gills; and it is by having repreſented as lungs the forked ſwimming bladder of ſome of them, that Dr. Garden cauſed the miſtake of Linnæus.

The larvæ or tadpoles of the batracian reptiles only, that is to ſay, of the ſalamanders and frogs, the tree-frogs and toads, have both branchiæ and lungs; breathe, at leaſt for a certain time, both the air in its elaſtic ſtate, and that which is contained in water; conſequently participate equally the nature of aerial and aquatic animals; and may, therefore, without impropriety, bear the name of *amphibious* in its moſt ſtrict acceptation. But with theſe it is only a tranſitory, and with ſome perhaps only a momentary ſtate. As their lungs are developed, their branchiæ are obliterated, and they entirely loſe the latter, often even before reaching their full ſize, and particularly before they are capable of reproduction. Such, at leaſt, is the reſult of obſervations on all the tadpoles of theſe climates, on all which it is poſſible to follow in their various developements.

But naturaliſts have obſerved three other animals, uniting, like our tadpoles, the two kinds of reſpiratory organs, not appearing to loſe any of them at any epocha of their lives, and of ſuch form and ſize, that it is ſaid in the countries which they inhabit, no perfect reptile is known, of which they could be the larvæ. Are theſe creatures perfect animals—true permanent amphibia? Should they be conſidered an intermediate claſs between reptiles and fiſhes? We proceed to examine this queſtion, obſerving, in the firſt place, that the ſtructure of the circulating organs in the common tadpoles, which has been deſcribed in a former part of this article, muſt be kept in view as a point of compariſon.

Anatomy of the Siren Lacertina.—This animal is common in the rivers and marſhes of South Carolina, and is remarkable for poſſeſſing only the fore feet. Dr. Garden ſent an individual to Linnæus, accompanied with a deſcription, in which he mentioned the ſimultaneous exiſtence of branchiæ and lungs, and declared that there is no ſalamander in Carolina large enough to have been produced from the ſiren. Hence Linnæus determined to eſtabliſh for it a particular order of reptiles, the amphibia meantes. Nearly at the ſame time it was deſcribed in the Philoſophical Tranſactions by Ellis, whoſe deſcription was accompanied with an anatomy of the animal by Mr. J. Hunter. Yet ſeveral naturaliſts conteſted the reſult of theſe examinations. Pallas, Hermann, Schneider, and others, conſidered that it might be a larva. Camper, on the faith of an imperfect ſpecimen, in which no lung could be found, concluded it was a fiſh, (Kleine Schriften, tom. iii. pl. 1. p. 20.); and Gmelin, on his authority, claſſed it among the eels.

Cuvier has had an opportunity of diſſecting and deſcribing it. His account, which ſettles the diſputes ſatiſfactorily, is contained in the Recherches already quoted, and has furniſhed the materials of the following deſcription. The facts are repreſented in the 11th and 13th plates of the firſt volume of Humboldt's Recueil d'Obſervations de Zoologie et d'Anatomie comparée. The length was half a metre, but it reaches ſometimes between 30 and 40 inches. The body is much like that of an eel. The anus is at 15 centimetres from the poſterior extremity. The head is not ſeparated from the body by a neck: it is rounded, and terminated by an obtuſe ſnout. The mouth is ſmall, and the lips, which are not conſiderable, are not ſupported by any bones, as they ſometimes are in fiſhes. The noſtrils are two ſmall holes near the edge of the upper lip. The eyes are placed above the angle of the mouth: they are round, ſmall, without eye-lids, and only viſible becauſe the ſkin, in paſſing over them, becomes tranſparent. You may ſkin the head, like that of an eel, without injuring the eye-ball.

The openings of the gills are three vertical ſlits placed in ſucceſſion behind the head: through them the water from the mouth is diſcharged. But there are no gills within, as in the lamprey for example; although Garden, Ellis, and Camper ſuppoſed it. The only branchiæ are three tufts or fingers, attached to the ſuperior angle of the ſlits, to which Ellis and Garden gave the name of opercula, but of which Linnæus recognized the true nature. There are ſurely only three on each ſide, of which the firſt is the ſmalleſt, and the third the largeſt. The different ſtatements concerning their number, which embarraſſed M. Schneider, ariſe from the name having been given to different parts. For example, Linnæus, who rightly deemed the tufts to be branchiæ, reckons three, without opercula (branchia ad latera colli utrinque tria, exſerta); but Garden, who conceived that the branchiæ were connected to the arches, ſays there are four, with three opercula, or one operculum of three lobes.

Each of the tufts conſiſts of a large fleſhy and conical pedicle, of which the inferior edge is divided into two rows of appendices, which are themſelves again twice divided in the ſame manner. The animal muſt have the power of moving theſe branchiæ in every direction: the net-work of branchial veſſels is expanded on their ramifications.

The fore feet, ſhort and ſlender, are placed a little behind the branchial apertures. There are four fingers, of which the laſt phalanges are pointed, but not furniſhed with nails. There is not the ſmalleſt appearance of ſcales on the ſkin.

Oſteology.—Although the individual examined by Cuvier had not reached its full ſize, oſſification was conſiderably advanced. The cranium, lower jaw, and ſpine, were perfectly oſſified. On the large bones of the arms there were epiphyſes, and the ſcapula was almoſt entirely cartilaginous. The latter bone remains conſtantly in this ſtate in the ſalamanders. The branchial arches were entirely cartilaginous, and probably continue ſo, as no point of oſſification could be obſerved, although the os hyoides and its branches were already almoſt completely hardened.

From the head to the end of the tail there are ninety vertebræ: the anus is oppoſite to the forty-fifth, yet it is far from being oppoſite to the middle of the body, becauſe the vertebræ of the tail, particularly towards its end, are much ſmaller than the others. The land ſalamander has thirty-eight, and the aquatic about forty. The pelvis is ſuſpended oppoſite to the fifteenth or ſixteenth, in the former; to the fourteenth or fifteenth, in the latter. There is not the ſmalleſt veſtige of pelvis or hind leg in the ſiren: there is not even any germ of theſe parts, although they exiſt in the tadpole at all ages. It is, therefore, very certainly never deſtined to have hind legs. There is a kind of imperfect pelvis, even in the ophiſaurus (anguis ventralis, glaſs-ſnake), a true ſerpent, though analogous to the lizards in ſome points, but never poſſeſſing hind legs.

Eight vertebræ only of the ſiren, from the ſecond to the ninth,

ninth, support ſmall ribs, or rather very ſhort falſe ribs. In the land ſalamander there are twelve or thirteen, and in the aquatic eleven. Theſe ſmall ribs, loſt among the muſcles, are only obſerved in the genus of ſerpents called cæcilia, where they exiſt in great number.

The individual vertebræ are very differently ſhaped from thoſe of ſalamanders, frogs, and cæcilia. The body is terminated before and behind by a hollow cone filled with cartilage, which unites it to the adjoining bones, as in fiſhes. There is a ſmall longitudinal prominence below; and above, a criſta holding the place of the ſpinous proceſs, and bifurcated behind. The four angles of the ſuperior ſurface are occupied by the articular apophyſes, of which the anterior have their articular faces turned upwards, and the poſterior downwards. The tranſverſe proceſſes are formed of two triangular plates: one, inferior and horizontal, comes off from the whole ſide of the body of the vertebræ; the other ſlants backwards, and reaches from the anterior articular proceſs to the poſterior edge of the preceding. At the extreme point of their union we find the ſurface to which the rudiment of rib is articulated, in thoſe vertebræ which have ribs.

None of the allied genera reſemble the ſiren in the form of the vertebræ; and their ſingular ſhape would alone be ſufficient to authoriſe us in conſtituting a ſeparate genus for this animal. The head leads equally to the ſame concluſion, being entirely different from that of the ſalamander, and other reptiles. The noſtrils, ſimply excavated at the ſides of the ſnout, do not penetrate into the mouth: neither the orbit nor the temporal foſſa is cloſed below. Hence the upper jaw-bone does not form a complete bony circle; its anterior part only is formed by the intermaxillary bones, and has no teeth. Thus the ſiren has only palatine teeth attached to the two plates, and not implanted in the palate. The prominence, having the ſurface for the articulation of the lower jaw, is much ſhorter than in the ſalamander. The lower is articulated with it by a convex ſurface, ſhaped like the ſegment of a ſphere: its coronoid proceſs is very ſhort; each of its branches is compoſed of three pieces at leaſt. The teeth are attached to their internal ſurface, and not implanted in their edges. The head is articulated to the neck by means of two condyles.

The bony apparatus of the branchiæ reſembles that of fiſhes, with a few ſlight differences. A longitudinal bony piece bears, at each of its extremities, a pair of tranſverſe portions. Each of theſe anterior portions is joined to a cartilage, which aſcends behind the head, ſuſpended by a ſtrong ligament to the ſides of the occiput: it is analogous to the piece which ſupports the radii of the branchioſtegal membrane in fiſhes. But here there are no radii; and there is even a ſolution of continuity between this piece and the firſt arch of the branchiæ. This firſt arch, the largeſt of all, is joined to the poſterior tranſverſe piece mentioned above. The three others are joined to a third bony piece, ſimilar to the preceding, but ſuſpended behind it, and not articulated to the longitudinal piece. Theſe four arches are ſimply cartilaginous. Their ſuperior extremity is ſuſpended to the ſecond rib by a ligament, but not articulated to it. Their edges exhibit a ſeries of ſmall fine denticuli, which border the three branchial apertures: the anterior edge of the firſt arch, and the poſterior of the laſt, not concurring in the formation of any opening, have none of theſe denticuli. The ſkin is immediately attached to theſe arches, and they ſupport nothing, as we have already ſtated, analogous to the branchiæ of fiſhes. The tufts, which have no bone in their interior, are the only branchiæ.

The oſteology of the legs is the ſame as in the ſalamander: it compriſes a ſlender ſcapula, terminated above by a cartilaginous dilatation; a large cartilaginous plate, which may be regarded as a double clavicle, analogous to that of the frog, the uſe of which is to protect the front of the cheſt; a humerus; two bones of the fore-arm; a carpus, of which the bones were too ſmall and ſoft to be reckoned; a metacarpus and phalanges.

Organs of Senſe.—The ear is the only one which Cuvier could obſerve accurately; it ſeemed to reſemble that of the ſalamander. In the outer ſide of the bone incloſing the labyrinth, is an oval aperture, ſimply cloſed by a cartilaginous plate, covered by ſoft parts.

Organs of Circulation and Reſpiration.—There is a ſingle auricle of conſiderable ſize, with its circumference denticulated, receiving all the blood of the body, and the lung; two large valves are placed at the mouth of the vena cava. This auricle communicates with the ventricle by a ſingle orifice; and the blood departs from the latter by the aorta only. The heart is therefore exactly the ſame as that of the frog, the ſalamander, and of fiſhes.

The trunk of the aorta, or rather of the veſſel, which in fiſhes is called the branchial artery, is furniſhed with fleſhy and thick ſides, and its baſis has three ſtrong valves. It divides into three branches on each ſide for the three branchial tufts, and no branch goes from it to any other part. Theſe arterial branches become attached to the three cartilaginous arches in their way to the branchiæ; but they form no plexus on them, which proves that branchiæ are not attached to theſe arches as in fiſhes, and as Garden, Ellis, and Camper imagined in the ſiren.

Arriving at the branchial tufts, the arteries ramify over all their ſubdiviſions, and the veins bring back the blood in a contrary direction. The ſame circumſtances may be ſeen in the branchiæ of young aquatic ſalamanders, in which perhaps the circulation of the blood can be more eaſily obſerved with the microſcope, than in any other animal organ.

Having quitted the tufts, the branchial veins aſſume the texture of arteries, and join together, towards the ſpine, to form the deſcending aorta; but they produce, before their union, the branches which in other animals ariſe from the aſcending aorta, that is, thoſe of the head, arms, and lungs: the latter come from the third of theſe branchial veins converted into arteries.

The lungs are two long cylindrical bags, extending to the poſterior end of the abdomen, and then bent forwards. The veins and arteries form a looſe network on their membrane. Air enters them through a larynx placed on the os hyoides, and opening between two ſmall rounded margins placed vertically. A very ſlight cartilaginous prominence is obſervable on each ſide in its interior, and the glottis is between theſe: but there is no chorda vocalis with a ſharp edge. Yet it does not follow that the obſervers, who have aſcribed a voice to the ſiren, are inexact; for the approximation of the two prominences juſt mentioned would be ſufficient for its production.

The trachea is a ſimple membranous, white, and thick canal, without any perceivable cartilaginous rings.

Organs of Digeſtion.—We have already mentioned the jaws and teeth. The tongue is not fleſhy, nor very moveable: it is ſupported, as in fiſhes, by the anterior extremity of the os hyoides. It does not reſemble that of the ſalamander, and much leſs that of the frog, both of which are more free behind than in front, and have a very glandular ſurface.

The œſophagus is folded longitudinally. The coats of the ſtomach are moderately thick; it firſt ſwells a little, then

then becomes mufcular and contracted, and is narrower than the duodenum. The latter is the wideft part of the inteftine, which becomes fmaller towards the anus. Although longer than the abdominal canal, and confequently forming feveral flight turns, it exhibits no great folds. There is no cæcum, nor any remarkable change of ftructure to point out the diftinctions of different kinds of inteftine. The pylorus has no valve; the mucous membrane of the ftomach is fmooth; that of the inteftine has papillæ like fmall fcales.

The canal is fupported by two parallel mefenteries, of which the right adheres to the whole length of the liver. There is no omentum.

The liver is black, elongated, and occupies more than three-fourths of the length of the abdomen. The gall-bladder is lodged in a deep groove towards its middle, and furnifhes a fingle canal, opening into the inteftine a little beyond the pylorus. No duct could be perceived coming directly from the liver, but fuch a one might have been confounded with the numerous mefenteric veffels.

A flender and very long fpleen is attached to the mefentery of the left fide, and occupies more than three-fourths of the length of the abdomen.

Organs of Generation.—The individual examined by Cuvier was a female. The ovaries were confiderably developed, about one-fourth of the length of the abdomen, oblong, compofed of lobes, filled with very vifible ova, although fo flaccid that they probably did not approach to the fize which they would have reached in the feafon of reproduction. A fhort and ftraight oviduct was clofely connected to the kidney: this part was very different from the long tortuous tubes of the frog and falamander, and approached to the ftructure of fifhes.

Organs of Secretion.—The kidnies were fmall, well fupplied with blood-veffels, and fituated at the fides of the rectum. The bladder elongated, and not divided as in frogs.

The conclufions drawn by Cuvier from the preceding account are; 1. That the firen, into whatever ftate it may pafs, is a diftinct animal, different in all the details of its organifation from the falamanders and their larvæ which we are acquainted with.

2. That it is very certainly not deftined to poffefs hind feet, and confequently is a biped reptile.

3. There is no reafon to fuppofe that it ever lofes its branchiæ, fince it is found to poffefs them at the largeft fize to which we know of its reaching, and the unanimous teftimony of thofe, who have feen the animal in its native country, proves that no individual has ever been feen without them.

4. That it is effentially different from fifhes in its ofteological ftructure, and even in the organifation of the branchiæ.

5. That it therefore conftitutes a particular genus of batracian reptiles, preferving always the double refpiratory organs; and may be confidered as a permanent larva of that family.

Anatomy of the Proteus Anguinus.—This animal was firft noticed in the Synopfis Reptilium of Laurenti, in 1768. Scopoli gave a more minute account of it in 1772, in his Annus quintus Hiftor. Nat. p. 75. Naturalifts were divided in opinion, whether it fhould be regarded as a perfect animal, or only as the larva of fome reptile. An excellent defcription of it, both as to its external characters and ftructure, was publifhed in the Philofophical Tranfactions for 1801, pt. 2, by Dr. Schreibers of Vienna, in a paper entitled "An hiftorical and anatomical Defcription of a doubtful amphibious Animal of Germany, called by Laurenti Proteus Anguinus." Cuvier has fince defcribed it in his Recherches fur quelques Reptiles douteux.

The individual examined by Cuvier was 0.25 of a metre in length, and of the fize of the little finger: Mr. Schreibers faw one of 0.33, or 13 Englifh inches. The body is flightly compreffed, and grooved at the fides, like the firen. The tail is more flattened, and furnifhed at its edges and end with a fin, which does not reach either above or below farther than the anus. The feet are flender; the knee and elbow being about their middle, and directed as in the falamanders; the fore-feet are terminated by three equal toes without nails, the hind-feet by two only; a combination, which is hitherto unique in the animal kingdom.

The head has fome refemblance to that of an eel; the opening of the mouth is of moderate fize, and furnifhed with thin lips. The noftrils are a longitudinal flit on each fide, parallel to the fide of the upper lip. No eye is perceptible externally; but when the animal is fkinned, it is feen under the integuments as a black point, about the thirtieth of a line in breadth.

In the depreffion produced by the mufcles at the fides of the cranium are feen the openings of the branchiæ. They are three, covered in fome degree by a prominence of the fkin, fupported by a mufcular ftratum. The branchiæ are three fmall appendages, of a red-blood colour in the living animal.

The fkin is whitifh, foft, fmooth, and prefents fome fmall prominences, when examined with a magnifying glafs.

Ofteology.—When the mufcles, that fwell the cranium externally, are removed, it appears flat, and quite on a level with the face; the latter terminates in a point in front. The middle of the cranium has its fides parallel; the pofterior part fwells out in the fituation of the prominences to which the lower jaw is articulated, which are directed forwards. Behind, the occiput has two lateral criftæ for the mufcles. The head is articulated with the atlas by two condyles: the under furface of the cranium is very flat.

There is no diftinct zygomatic arch, orbit, or temporal foffa.

All round the upper jaw is a row of fmall pointed and vertical teeth; and in front only a fmall additional row before the others. The inferior jaw has a fingle row of teeth. Its two branches are nearly rectilinear, and make an angle of about 45°. It has no afcending branch, and the coronoid procefs is inconfiderable. All thefe parts are well offified and firm; and, although the futures are ftill vifible, we cannot fail to fee that the bones belong to an animal very near the adult ftate.

The bony apparatus of the gills is much more firm than in the firen or axolotl, and fomewhat differently compofed. The hyoideal branches are flender, and fufpended to the fides of the cranium behind the articulation of the lower jaw. The os hyoides is fhort and thick, and fupports behind two pieces equally fhort and thick, which diverge a little. The firft arch of each fide, which is the largeft, is articulated to the extremity of one of thefe pieces, and has the two other arches attached to its pofterior edge.

There are fifty-fix vertebræ: the pelvis is attached to the thirty-firft; and the twenty-five following belong to the tail. Six only of thefe vertebræ, beginning with the fecond, fupport rudiments of ribs, ftill fmaller than thofe of the falamander and the firen.

All the vertebræ, excepting the laft of the tail, are perfectly offified: their form is peculiar to this fpecies.

Organs of Digeftion.—The tongue is fhort, with little power of motion in front, and fupported by the anterior extremity of the os hyoides. The inteſtinal canal extends nearly in a ſtraight line through the abdomen. The œſophagus is folded longitudinally; and the ſtomach is only a rather larger portion of the canal, not marked by any conſtriction. There is neither cæcum nor large inteſtine. An oblong liver, pointed at the two ends, of a blackiſh-grey colour, with two notches in its left edge, occupies about two-thirds of the length of the animal. A large gall-bladder, attached to the internal ſurface of the liver, pours the bile into the inteſtine by a ſhort canal. The pancreas is ſmall and narrow, and attached to the inteſtine oppoſite to the gall-bladder. An oblong narrow ſpleen is attached to the meſentery, and is about one-fourth of the length of the liver. The meſentery is ſimple, and has the uſual veſſels. There is no omentum.

The Organs of Circulation are the ſame as in the ſiren, except that the branchial veins unite together, to form the deſcending artery, rather lower down.

Organs of Reſpiration.—The branchiæ are moved, as in the axolotl, the ſiren, &c.: but no reptile has ſo ſmall a proportion of lung as the proteus. There is no larynx, properly ſo called, only a ſmall opening at the bottom of the pharynx, which is the entrance of a common creſcent-ſhaped cavity, the angles of which are prolonged to form the lungs. The latter are merely two very thin membranous canals, terminated by a ſlight dilatation, preſenting in their interior no diviſion into cells, and exhibiting very few blood-veſſels on their parietes. When we conſider how little difference there is between ſuch lungs and the forked air-bladders of ſome cartilaginous fiſhes, we can hardly help concluding that there is ſome analogy between the two organs.

Organs of Generation.—In the female diſſected by Cuvier, oblong lobed ovaries, full of very diſtinct ſmall ova, were ſituated towards the lower part of the abdomen, at the ſides of the rectum. Very long oviducts, making ſeveral turns, like thoſe of the ſalamander, aſcend to the anterior third part of the cavity.

Organs of Secretion.—There are kidnies and a bladder, as in the ſalamanders: the former are very long, and paſs high up in the abdomen.

All theſe obſervations, and particularly thoſe concerning the oſteology, make it clear that the proteus is a particular animal, different from all hitherto known: they alſo make it very probable that it is an adult animal, not deſtined to undergo any further change of ſtate.

A proteus taken alive threw up from its ſtomach many ſhells of the genus helix, but it would not take theſe ſhells or any other food, and became daily more languid and weak. It ſeemed, when alive, very torpid, and moved but ſeldom; it ſwam, however, ſometimes, with the help of its broad tail, very ſwiftly, in every direction. The firſt days it crept ſlowly on the bottom, and ſeemed to look for food; it often took a ſhell into its mouth, but gave it out again, ſwallowing none. Several times it roſe to the ſurface, ſtretched its head out of the water, and took in air, but returned directly to the bottom. It uſes its feet in creeping on the bottom, and in aſcending along the ſides of the veſſel, if of wood. It creeps very ſlowly or deliberately, inſomuch that this motion ſeemed quite characteriſtic of the animal.

It often produces a hiſſing kind of noiſe, pretty loud, more ſo than one ſhould expect from the ſize of the animal, and reſembling that produced by drawing the piſton of a ſyringe.

All the habits of the proteus deſignate a ſlowneſs and weakneſs agreeing very well with the exceſſive ſmallneſs of its pulmonary organs, and the very inconſiderable extent of their ſurface.

It is a very rare animal, having been hitherto found, and that in very ſmall numbers, only in thoſe lakes of Carniola, which are celebrated on account of their ſubterranean communications and the ſingular phenomena which reſult from them. That of Cirknitz is the moſt famous, and is regarded as the ſource of all the others. According to Laurenti, the firſt proteus was found in this: but Schreibers aſſures us that it only inhabits the lake called Sitticher See, communicating with the Cirknitz; and that it is thrown out in the overflowings, which occur once or twice a-year.

Cuvier thinks it probable that its natural abode is in the ſubterranean communications extending from one lake to the other. It has, in fact, all the characters of a ſubterraneous, as well as of an aquatic, animal. Its ſmall eyes, concealed and rendered uſeleſs by an opaque ſkin, recall to us the blind rat (zemni, mus, or ſpalax typhlus) which lives under ground, and has exactly the ſame organization.

In a letter to Cuvier, Schreibers informed him that, ſince the publication of his paper in 1801, he has met with ſeveral individuals, all perfectly alike, among which he had in vain ſought for one without the branchiæ. That he himſelf has ſome, which have been two years in his poſſeſſion, alive and well, although they have taken no food the whole time.

For the external figure and anatomy of this animal, ſee the plates ſubjoined to Dr. Schreibers' paper in the Phil. Tranſ. and pl. 13 of the Recueil d'Obſ. de Zool. et d'Anat. Comparée de Humboldt, v. 1.

Another of theſe doubtful animals has been figured in the Annales du Muſeum, v. 10. p. 230. pl. 17. under the name of protée, or ſalamandre tetradactyle, by Lacépéde, who has there deſcribed its external conformation. It poſſeſſes branchial appendages, eyes covered by the epidermis, and two rows of fine teeth. As only the ſpecimen deſcribed in the above quoted work is known (without any information about the quarter whence it came), its anatomical ſtructure has not been examined. All the appearances lead us to expect an internal organization like thoſe of the proteus and ſiren.

The following are the principal ſources of information on the ſubjects of the preceding article. Cuvier, Leçons d'Anatomie Comparée. Blumenbach's Manual of Comparative Anatomy; alſo his Specimen Phyſiologiæ comparatæ inter Animalia calidi et frigidi ſanguinis, 4to. Goett. 1787; or in Commentation. Soc. Reg. Scient. Goettingenſ. v. 8. Daudin, Hiſtoire Naturelle des Reptiles, in the 8vo. edition of Buffon by Sonnini, 8 tomes. Brongniart, Memoire ſur une nouvelle Claſſification des Reptiles. Lacépéde, Hiſtoire Naturelle des Quadrupedes ovipares et des Serpens. Latreille, Hiſt. Nat. des Salamandres de France, avec figures. Schneider, Hiſtoria Amphibiorum. Schoepff, Hiſtoria Teſtudinum, 4to. Schneider, Naturgeſchichte der Schild-kröten. Roeſel, Hiſtoria Ranarum. Memoires pour ſervir à l'Hiſtoire des Animaux. Tyſon's Anatomy of a Rattleſnake, Phil. Tranſ. v. 13. Swammerdam Biblia Naturæ. Charas, Nouvelles Expériences ſur la Vipère. Caldeſi, Oſſervazioni Anatomiche intorno alle Tartarughe, 4to. Hermann, Tabulæ affinitatum Animalium. Spallanzani's Diſſertations. Cuvier, Recherches ſur les Reptiles douteux, in Humboldt, Recueils d'Obſerv. de Zool. et d'Anat. Comp. v. 1. Various papers by Cuvier and Geoffroy St. Hilaire, in the Annales du Muſeum.

Reptiles are likewiſe uſed, abuſively, for plants which creep on the earth, or on other plants, as wanting ſtrength of ſtalk to ſuſtain themſelves.

Such

Such are cucumbers, melons, &c.; fuch alfo are ivy, the vine, and bryony.

REPTON, in *Geography*, a confiderable town in the hundred of Repton-and-Grefley, and county of Derby, England, is fituated near the banks of the river Trent, at the diftance of eight miles S.W. from the town of Derby, and four N.E. from Burton-upon-Trent in Staffordfhire. Among antiquaries it is celebrated as the fcite of the capital of the Mercian monarchy, and the burial-place of feveral of its fovereigns. At that period it was called Hreopandune; and is conjectured by fome to have rifen upon the ruins of the Roman ftation Repandunum; and the town is called Reppendune in ancient deeds. In the Saxon annals Repton is faid to have been noted for a noble monaftery of men and women, eftablifhed, under the government of an abbefs, previous to the year 660. This abbey was deftroyed by the Danes in the reign of Buthred, the laft king of Mercia, and remained in a defecrated ftate till the year 1172, when it was refounded as a priory by Matilda, widow of Ranulph, fecond earl of Chefter, who beftowed upon the monks the tithes of Repton, and confiderable eftates in the neighbourhood, befides Bartlow in Effex, and lands at Granfden, in Huntingdonfhire. At the diffolution its revenues were eftimated at 167*l.* 18*s.* 2*d.* In the original ftructure were depofited the remains of feveral of the Mercian kings; as were likewife thofe of Rynechardus, brother to Sigebert, king of the Weft Saxons. Some portions of the later buildings are yet in exiftence, being converted into a fchool-houfe and apartments for the mafter and ufher. The fchool-room, as appears from the windows and other traces, was either the refectory, or the hall, of the priory. It is fupported by a row of ftrong round columns, with pointed arches. At the northern extremity of this room was the dormitory; and on the eaft fide were fituated the cloifters, the area of which is now a garden. Adjoining the cloifters ftood the church which Fuller, in his "Church Hiftory," defcribes as an elegant and fpacious ftructure, fupported in the interior by pillars of alabafter, fragments of which have been occafionally laid open. Foundations of other buildings, befides thofe mentioned, may ftill be plainly traced in various directions; and on the fcite of the prior's lodging is a manfion called Old Trent, built about a century ago, which difplays, towards the water, a curious brick tower with an ornamental cornice, part of a former building, erected by Prior Overton in the reign of Henry VI.

Repton confifts chiefly of one ftreet of fcattered houfes, extending about a mile in length, and watered by a fine ftream, which difcharges itfelf into the Trent. At the lower end of the town ftands the parifh church, a large, handfome edifice, ornamented with a fine fpire two hundred feet high. Tradition affirms that the prefent is the third church which has occupied the fame fcite; and there can be no doubt that parts of it are of different and diftant dates. The nave and fide aifles feem to be of the reign of Edward III.; but the chancel is probably more ancient, as its columns are maffive, and its arches femicircular. Beneath this part of the church is a crypt, bearing a ftrong refemblance, in form and ornaments, to the crypt under Canterbury cathedral, and alfo to that under St. Peter's in the Eaft, at Oxford. In the interior of this building are feveral handfome monuments to the memory of the Thacker family. Within a clofe behind the church, a labourer fome years ago difcovered a cemetery, which contained among many other human fkeletons, one of an extraordinary fize, meafuring nine feet in length. This difcovery is noticed by Dr. Pegge in the Philofophical Tranfactions for the year 1734. An old ftone crofs, confifting of a fingle fhaft, placed upon eight octagonal fteps, ftands in the area fronting the church. The parifh of Repton, according to the parliamentary returns of 1811, contains 326 houfes, and 1648 inhabitants, who are chiefly engaged in purfuits connected with agriculture.

At a fhort diftance from Repton is Sudbury, the feat and property of the family of Vernon, which is of great antiquity, deriving its defcent from Richard de Vernon, a Norman lord, who accompanied the Conqueror to England; and was one of the feven barons created by Hugh Lupus, the great earl of Chefter. Sir Ralph de Vernon, who was alive in the reign of Edward II., is faid to have reached the extraordinary age of 150 years. Sudbury church, an ancient fabric, ftanding in the garden near the houfe, is decorated with many fepulchral tombs to members of this family. One, in commemoration of Catharine, daughter to the late lord Vernon, is remarkable for the beauty of the epitaph, which was written by William Whitehead, poet-laureat.

At Egginton, on the banks of the river Dove, weft of Repton, is a feat of fir Henry Every, whofe family was originally feated in Somerfetfhire. Part of the old manfion here was deftroyed by fire in the year 1736, and the prefent houfe then erected on its fcite.

Bretly park, the feat of the earl of Chefterfield, is about three miles S.W. of Repton. About three miles E. of Bretly is Calke hall, the feat of fir Henry Harpur, bart. The houfe is a fpacious quadrangular edifice, feated in a park furrounded by eminences. Beauties of England and Wales, vol. iii. by John Britton and E. W. Brayley, 1802.
